# THE LANCET.

Journal of British and Foreign Medicine, Surgery, Obstetrics, Physiology,
Chemistry, Pharmacology, Public Health, and News.

IN TWO VOLUMES ANNUALLY.

VOL I. FOR 1902.

---

*EIGHTIETH YEAR.*

---

EDITED BY THE PROPRIETORS:
THOMAS H. WAKLEY, F.R.C.S. ENG.,
AND
THOMAS WAKLEY, JUN., L.R.C.P. LOND.

---

LONDON:
AND PUBLISHED BY THE REGISTERED PROPRIETORS, AT THE OFFICES OF "THE LANCET," No. 423,
AND Nos. 1 & 2, BEDFORD STREET, STRAND.

MCMII.

# INDEX TO VOLUME I., 1902.

☞ *Readers in search of a given subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral, Heart and Cardiac, Liver and Hepatic, Bicycle and Cycle, Child and Infant, Enteric and Typhoid, Bronchocele, Goitre, and Thyroid, Diabetes, Glycosuria, and Sugar, Eye, Ophthalmic, and Vision, &c., &c.*

A

Abbott, Mr. J. H. M., Tommy Cornstalk (review), 1191

bdominal hysterectomy (or pan hysterectomy), 14, 163, 310, 448, 660, 672; injuries of difficult diagnosis, 159; contusion, 247; tumour, solid, with ascites, 339, 478; viscera in pregnancy, 524; aneurysm, 670; cyst, 671; inflammation, the quiescent or latent period in, 1305, 1321; operations, clamp for, 1408; inflammation, the simulation of, by thoracic, 1414; wall, relaxation of the, under anæsthetics, 1523

Abdominal (see also Intra-abdominal)

Aberdeen University; extension scheme, 125, 200, 265; arts class reunion, 125; dinner of King's College class, 200; an "at home," 265; students' representative council, 265; a legacy, 408; graduation, 704; pass-list, 993, 1148

berdeen University Club, London, 1271

berdeen public library, 200, Sick Children's Hospital, 408; Royal Infirmary, 481; Convalescent Hospital, 481; Royal Lunatic Asylum, 481

berystwith Workhouse, 60

biotrophy, 1003

bortion, statistics of, 1125, 1144

bortion, the procuring of, 414

bscess, cerebral, 455, 1217; subdural, 455; hepatic, 460; of the appendix, 618; cerebellar, 520, of the liver, 1452, 1467, 1525

etanilide, poisoning by, 243

etylene, dangers of, 763; as an illuminant in warfare, 839

etylene light in omnibuses, 608, 790, 903

hondroplasia, 838

hondroplasic dwarfs, 931

ne, staphylococcus vaccine in, 874

inomycosis, case of, 306

tinomycosis of the ovary, 164; of the tongue, 147

tions at law: against the corporation of Glasgow, 200; against a pharmaceutical hemist, 623; against medical men, 680, 695, 02, 933, 1073

ami, Dr. J. G., blastoma, 1562

amkiewicz, Prof. Albert, cancroin, 288, 322, 934

diment, disappearance of the, from antimicrobic sera, 18

enoids, removal of, improvement of patient after, 166

enoids, treatment of, 672

hesions, recent, a new method of breaking down, 87

renalin chloride in the mastoid operation, 55

ulteration (see Declared)

vertisement, 789

ertisements, indecent, 565; disgusting, 224; filthy, 1294, 1509

hesiometer, a new, 667

ica, South, Guide to (review), 33

ica, South, plague in, 46, 177, 248

ica, South, typhoid fever in, 139

ica, South (see also Services, South African, War in South Africa)

ca, West (see West African)

r Care Association (i.e., for assisting per- ns discharged from lunatic asylums), 484,

Age, influence of, upon optic neuritis, 1687

Aid (see First aid, Medical aid)

Ailments, minor, a plea for the study of, 757

Air, ionisation of the, by x rays, 166

Air (see also Atmosphere, Liquid air, Open air, Sewer air)

Aitchison, Mr. James, the Spectaclemakers' Company, 921

Albuminuria, hypostatic, of splenic origin, 585, 594

Albuminous expectoration, 1616

Alcohol and amblyopia, 911; and tobacco, the poisonous coöperation of, 327

Alcohol, is it a stimulant? 311

Alcohol question in Russia, 189

Alcohol (see "Columbian spirits," Drunkenness, Intemperance, Licensing, Local option, Methyl alcohol, Motor, Public houses, Tipping)

Alcoholic peripheral neuritis, etiology of, 385, 390

Alcoholism, hereditary sequelæ of, 837

Aldershot, small pox accommodation at, 485

Alderson, Dr. F. H., saddle soreness, varicose veins, 1073

Alexander, Dr. D. A., phthisis, 1073

Alexander, Dr. William, epileptics, 805

Alginoid of iron, 676

Allan, Dr., specimens shown, 454

Allbutt, Prof. T. C., army medical service, 385

Allingham, Mr. H. W., "What's What," 550, gastric surgery, 590; the knee-joint, 731

Amblyopia, the production of, by alcohol, 911

Ambulance classes, the wrong teaching given to, 54, 117, 194, 255, 334, 401

America, North, Medical Directory of (review), 1406

America, the United States of, health of the navy during 1900, 115; small pox, 610, men in the navy not entitled to refuse certain surgical operations, 707; protection of the President, 707; Surgeon General of the Navy, 708

America or American (see also Anglo-American, NEW YORK, CORRESPONDENCE FROM)

American Authors, A Treatise on Surgery by (review), 171; Ophthalmological Society, Transactions of (review), 974; Journal of the Medical Sciences (review), 1118

"American specialists," 789

Americanists, international congress of, 1070

Ammonium chloride inhaler, 754

Ampulla of Vater, carcinoma of the, 1102

Anæmia, pernicious, nature and treatment of, 148

Anæmia, senile, 446; splenic, 668

Anæmia (see also Banti's disease)

Anæsthesia, chloroform, in heart disease, 202; during sleep, 911, 932

Anæsthesia produced by cocainisation of the spinal cord, 1051

Anæsthetic, a new local, 127, 1688

Anæsthetic inhaler, 1545

Anæsthetics, the teaching of, 122; administration of, during labour, 230, 276, 477

Anæsthetist and operator, 25

Analysis of plants, 468

Analyst, public, medical officer of health and, 686

Analysts, Public, Society of, 468; appointment and qualifications of, 760

ANALYTICAL RECORDS FROM THE LANCET LABORATORY.—Liquid petrolatum; Solution iron peptonate and manganese with arsenic; Terpin hydrate and heroin tablets; Functional tonic tablets; Petanelle foot powder; Old tawny port; St. Boniface spring water; Peptone Cornelis; Pastilles cocaine Bruneau; Various soaps; Kathreiner's patent malt coffee; Fibrous beef tea, 35, 36—Zoeco, 36, 208—"Tabloid" hydrarg. perchlor., gr. 1-16, et potass. iodid., gr. 5; "Emule" morphine and belladonna; Plasmon butter; Carlea cocoa; Aquarius water softener; "Bispep"; Lombardy butter; Vitalle oil; "Antifièvres" (Robert); Banana malted food (Boyd); Pine hop-bitters (Boyd); Antiseptic eau de Cologne (Boyd), 236, 237—Sterilised milk (Snip brand); Lecithine preparations (Clin) and the cacodylates (Clin); Scotch whisky, the All Malt brand (A.M.B.) No. 1 and No. 2; Sparkling moselle natural brut; Wand's pills, perles, capsules, and tablets; Alginoid of iron; Thyroglandin; Hovis food for infants and invalids (No. 1 and No. 2); Keto metal polish, 675, 676, 677—Newsholme's portable ammonium chloride inhaler; Virol; Casumen bread; Casumen biscuits; Rowntree's elect cocoa and Swiss milk chocolate; Tabloid aspirin; Pure fruit syrups; Toilet requisites, 754, 755—Billon's "Ovo" Lecithin pills and granules; "Churno" (butter substitute); Levurine; Medicated soaps; Anderson's tafelweine; Kalari biscuits, 1119—"Tabloid" mercury iodide yellow; Soloid sodium hydroxide and soloid pyrogallic acid; "Tabloid" Apomorphine compound; Casumen cocoa; Grain granules; Chinosol; Jams, pickles, and sauce; Allen's footease (powder); Aikman's lentil food; Grimmond's Yorkshire toffee; "Absorba" (body toilet powder), 1192—Beef karnoid; Friedrichshall mineral water; Purgatin; Triferrin; Solution adrenalin chloride, Cascara evacuant, Elixir glycerophosphates; Thermofuge; Irish whisky; Maltova, Banquet cream; The Armstrong beef and malt wine; Tabloid liquorice compound powder; Tabloid kino compound powder; Soloid microscopic stains; Soloid indigo test, Saluvino cordial; Digestive lentil flour, 1475, 1476—Tabloid urea; Tabloid hypodermic mercury succinimide; Various soaps; Antiphlogistine, Penfold's pure Australian wines; Banquet cream; Ceylon tea; Thalisal; Orion ruby wine; Natural Hungarian bitter water (Lord Roberts label); Medical and antiseptic tablets, 1837, 1838, 1839

Anarchism, the psychology of, 840

Anatomie, Lehrbuch der Speciellen Pathologischen (review), 170

Anatomy and physiology, address in, 633

Anatomy and Physiology, Journal of (review), 316, 1043

Anatomy in its Relations to Art (review), 97

Anatomy, Outlines of (review), 629, Practical, A Manual of (review), 752

Anatomy (see also Pathological, Pathologischen, "Pocket Gray")

Anderson, Mr. R. B., the late, appeal on behalf of his family, 57, 133, 208, 419, 537, 565, 864, 1116

Anderson, Fleet Surgeon R. W., court-martial on, 115
Anderson's College (see Glasgow)
Andrewes, Dr. F. W., revaccination, 85; tetanus, 1103
Aneurysm: aortic, 231, 445, 454; posterior ulnar recurrent artery, 231; abdominal, 670
Aneurysm in a horse, due to a parasite, 232
Angioma of the larynx, 228; of the scalp, 231
Anglo-American (see under MEDICAL SOCIETIES)
Aniline, cutaneous absorption of, poisoning by, 463
Animal, a new, 484
Animale (see Matière)
Animals, human tuberculosis inoculable in, 127; various, killed by hydrocyanic acid gas, 217
Animals, the Bodies of, The Direction of Hair on (review), 530
Ankle, compound dislocation of the, 451
Annamese medicine, 764
Annuity offices, 487, 640
Antarctic expedition relief fund, 765
Antenatal Pathology and Hygiene (review), 1697
Anthrax, gelatin cultures of, 376
Antibodies of the blood, 48
Anti-diphtheritic serum, preventive inoculations of, 482; the employment of, at Colchester, 1051
Antifebrin (see Acetanilide)
Antifièvres, 237
Anti-microbic sera, disappearance of the addiment from, 18
Anti-mosquito campaign, 554
Antiquity, medicine in, 1152
Antiquities, valuable collection of, 272
Antisepsis in hairdressing, 419
Antiseptic surgery, 211
Antiseptics, new, 392, 393
Anti-streptococcic serum in puerperal fever, 563
Anti-tetanin, intra cerebral injection of, in the horse, 609
Antitoxin, diphtheria, supplied to Poor-law medical officers, 124
Antitoxin, tetanus, 227, 303
Antitoxins, diphtheria and tetanus, not absorbed from the stomach and rectum, 375
Anti-typhoid inoculation, the results of, 964
Anti vaccinationist, the, 1074, 1127
Antivenene, Calmette's, 552
Anti-vivisection question, 978
Antrum (see Maxillary antrum)
Anus, imperforate, 158, 813
Anus, stricture of the, 27
Aorta, aneurysm of the, 231, 445, 454
Apes, cortical localisation in, 46; the anthropoid, the "blood relationship" of man and, 143
Appendicitis, blood in, 45; perforated gastric ulcer simulating, 441; operations for, the mortality after, 488; with localised suppuration, 518; with secondary abscess, 668; running an unusual course, 670; in which the appendix was lodged in, and adherent to, the femoral canal, 883; leucocytosis as a point of prognosis in, 1199; with general peritonitis, 1533
Appendicitis in British Columbia, 128
Appendix vermiformis, removal of the, after suppuration caused by appendicitis, 143, 257; intra peritoneal abscess of the, 518; threadworms in the, 539; inflammation of the, 1815
Apperson, Mr. G. L., Idler's Calendar (review), 34, 601
Appointments, weekly lists of, 64, 131, 205, 273, 344, 417, 486, 564, 638, 712, 787, 862, 932, 998, 1071, 1151, 1222, 1292, 1367, 1437, 1507, 1578, 1654, 1741, 1810, 1867
Appointments, various, 130, 204, 205, 249, 339, 342, 392, 404, 561, 708
Appointments (see also Medical appointments, Services)
Arc, a rapid oscillation high-tension, the ultra-violet light from, for the treatment of skin diseases, 285
Archambault, Dr. Leon, Examen Gynécologique (review), 1117
Armagh Union, nursing question in the, 126, 333
Armies, foreign, medical organisations of, 1482
Armstrong, Mr. William, spa treatment, 454
Army, water-borne diseases in the, prevention of, 639; spectacles in the, 905
Army at home, civil surgeons serving with the, 324
Army, the British, visual test used in, 811
Army, the Indo-Dutch, vital statistics of, 53; the French, hygiene in, 202
Army estimates, 617; the debate on the, 634
Army Medical Department, 683, 711
Army medical efficiency, 1548
Army Medical School: distribution of prizes,
Army Medical Service, the new director-general of the, 47; the new Warrant for the, 327, 466, 902, 912, 977; the advisory board, 398, 417, 471; examinations to be passed by the officers, 563
Army Medical Services (or Service), reorganisation (or reform) of the, 40, 385, 712, 1060
Army (see also Recruiting, Royal Army Medical Corps, Services, Soldiers, Troops)
Arrhenal (an arsenical compound), 623
Arsenic, estimation of (or testing for), 178, 480; in reduced iron, 837
Arsenic in beer, 385, 399, 466, 480, 485, 621, 837
Arsenic in diseases of the skin, 6
Arsenic (see also Arrhenal, Cacodylate, Iron)
Arsenical poisoning, Royal Commission on, 710, 786, 1150, 1221, 1435
Arsenical poisoning, beri-beri or? 703
Art, Anatomy in its Relations to (review), 97
Arthritis, experimental production of, by a diplococcus isolated from chronic arthritis, 90; accompanying ophthalmic neonatorum, 1529
Arthritis, Gonorrhœal (review), 459
Arthrotomies, observations on, 150, 1061
Arytenoid region, œdema of the, 597
Ascites, solid abdominal tumour with, 349, 478; frequent tapping for, 513; epiplopexy for, 524; chylous and chyliform, 667; lactescent, and cirrhosis of the liver, 1125
Aseptic surgery, 211
Ashby, Dr. H., peritonitis, 1096
Asparagus, The Book of (review), 1260
Asphyxia from pressure on the chest, 245
Asphyxiated, Society for Succouring the, 411
Aspinall, Mr. F. B., electric shocks, 660, 679
Assassin of President McKinley, trial, &c., of the, 289, 352
Assimilation, Digestion, &c., Disorders of (review), 1541
Assistant, the unqualified, on his own account, 466
Assistants' fees, 133, 208
Association centres, Flechsig's, 982
Assurance companies, medical men and, 276
Astragalectomy for talipes, 598
Asylum patients, cost of, 407; reports, 51, 113, 251, 397, 470, 603, 755, 844, 917, 1055, 1604; shyness, 976; Workers, Association of, 1552
Asylums, dysentery in (or asylum dysentery), 180, 307, 476, 588
Ataxia, Friedreich's, 150; locomotor, 230
Ataxic paraplegia, 307, 456
Ataxy after diphtheria, 909
Atmosphere, problems of the, 1148
Atmosphere of the Old Bailey, 101
Atresia, vaginal, 20
Atropine, history of, 911, 983
Auden, Dr. G. A., diphtheria, 1104
"Audi alteram partem," 551
Auditory tract, nerve-endings in the, 524; appreciation of mosquitoes, 531, 538
Auld, Dr. A. G., Pathology (review), 458; pulmonary œdema, 549, 775; physical diagnosis, 1526
Aural exostosis, 670
Aural (see also Nasal, Post-aural)
Auricle, the left, dilatation of, 307
Auscultation, the decay of, and the use of the binaural stethoscope, 369, 477, 6 8, 698

AUSTRALIA, CORRESPONDENCE FROM.—Plague, 203, 412, 780, 1432, 1805—Health of Sydney, 203, 1432—Friendly societies of New South Wales, 203—Prevention of tuberculosis, 203—Hospital affairs, 203, 413, 1432, 1805—Appointments, 204—Obituary, 204, 413, 781, 1433, 1806—Infectious diseases, 412, 780—Inquiry at Kew Asylum, 412—Coast Hospital, New South Wales, 413—Sydney Dental School and Hospital, 413—The right of a medical man to practise as a chemist, 413—Victorian Trained Nurses' Association, 413—Broken Hill Medical Institute, 413—Treatment of tuberculosis in Victoria, 780—Infectious Diseases Hospital, Melbourne, 781—Ptomaine poisoning, 781—Intercolonial Medical Congress, 781—Sydney University, 781—The Medical Act, New South Wales, 781—Committee *versus* staff of Women's Hospital, 781—Deniliquin Hospital, 781—Australasian Science Association, 855—The Queensland Branch of the Brit. Med. Assoc. and the Brisbane Associated Friendly Societies Medical Institute, 855—The profession and the friendly societies in New South Wales, 1433—Friendly societies and medical contracts, 1805—Nurses' examinations, 1806

Australasia, Medical Congress of, 1139
Authors, Society of, 65
Auto-intoxication as a factor in the production of cerebral and mental disorder, 683; cases of, 1832
Autolysis, 439
Avian filaria, 375
Axham, Mr. F. W., ethics, 257
Axillary mammæ, 312

B

Bacillus of Danysz, rats and the, 341, 390
Bacillus, the typhoid, in the blood, 390; at the sites of injuries, 464
Bacteria, hæmolysins produced by, 440, 566
Bacterial invasions, treatment of, by inoculations of the corresponding bacterial vaccines, 874
Bacteriological Diagnosis, Handbook of (review), 458
Bactériologie, Traité de (review), 1472
Bacteriologist, a public, for Nottingham, 1050
Bacteriologists, municipal, 47, 122
Bacteriology and sewer air, 1049
Bacteriology of arthritis, 90; of gangrene, 228; of anthrax, 376
Bacteriology, Determinative (review), 32
Bacteriology, Laboratory Course in (review), 600; Atlas and Principles of (review), 1259
Bacteriology (see also Diplococcus, Microbe, Pneumococcic, Streptococcus)
Bacteriolysis, 18
Bael treatment of dysentery, 66, 790
Bagdad, plague in, 552
Baldness in the barber's chair, 983; etiology of, 1294
Baldwin, Dr. W. W., cardiac disease, 551
Baldwin, Elizabeth L., Play of Man (review), 1189

## MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Bethnal Green Infirmary, N E—A case of cholesteatoma of the fourth ventricle (under the care of Dr Beatrice Knowles and Mr William Hall Peile, assistant medical officers), 1833
Birmingham General Hospital—An unexplained condition of chronic cyanosis, with the report of a case (under the care of Dr Saundby and Dr. J W. Russell), 515
County Antrim Infirmary, Lisburn.—Two cases of spina bifida treated successfully—the first by injection of Morton's fluid and the second by excision (under the care of Mr G L St George), 740
East London Hospital for Children, Shadwell.—A case of persistent omphalo-mesenteric duct, laparotomy, resection of the duct, recovery (under the care of Mr H Betham Robinson), 302
Edinburgh Royal Infirmary—A case of tabes with acutely developed ataxia in which great and rapid improvement resulted from Frenkel's plan of treatment (under the care of Dr Byrom Bramwell), 891
Egerton Hospital, Peshawar—A case of gastrotomy for removal of foreign bodies from the stomach recovery (under the care of Lieut Col G W P Dennys), 22
German Hospital, Dalston—Some cases of elephantiasis of the external genital organs following the removal of the inguinal glands (under the care of Dr J P zum Busch), 665
Great Northern Central Hospital—A case of extreme dilatation of the large intestine not due to stricture, terminating fatally (under the care of Dr H W Syers), 21
Hospital for Sick Children, Great Ormond-street—Two cases of abscess in the temporo-sphenoidal lobe presenting no lesion in the ears (under the care of Dr D. B Lees) 1247
Leeds General Infirmary—Two cases of Volkmann's contracture (under the care of Mr Ward, 372—A case of intussusception operation, recovery (under the care of Mr W H Brown), 691
London Temperance Hospital—A case of traumatic laceration of the right kidney, lumbar extravasation, partial nephrectomy, complete recovery (under the care of Dr W J Collins), 226—A case of perforated gastric ulcer, laparotomy, successful closure by suture, death eight days after from hæmorrhage from duodenal ulcer (under the care of W J Collins), 372—A case of solid ovarian tumour, laparotomy, enucleation, recovery (under the care of Dr W J *Collins), 1395*
Middlesex Hospital—A case of enteric fever in which Widal's reaction repeatedly failed, though a pure culture of the bacillus typhosus was obtained from the blood (under the care of Dr. W Essex Wynter), 1688
Monkwearmouth and Southwick Hospital—A case of amputation of the right shoulder and the right hip (under the care of Dr P A Pearcey), 1766
North Wimbledon Cottage Hospital—A case of tetanus successfully treated with antitoxin (under the care of Dr J. E Bates), 227
Northampton General Infirmary—A case of psoriasis rupioides (under the care of Dr F Buszard), 814—An anomalous case giving Widal's reaction (under the care of Dr P S Hichens), 1179—A case of localised disease in the optic thalamus, softening and hæmorrhage, death, necropsy (under the the *care of Dr F Buszard), 1396*
Paddington Green Children's Hospital—A case of tuberculous peritonitis with obstruction, laparotomy and short circuiting of the small intestine, recovery (under the care of Dr. G A Sutherland and Mr W Watson Cheyne), 158
Plymouth Borough Asylum—A case of perforating gastric ulcer, laparotomy, recovery (under the care of Dr W H Bowes and Mr R H Lucy), 1466
Royal Albert Edward Infirmary, Wigan—Remarkable cases of acute poisoning by dinitro benzene (under the care of Mr L H Monks), 89
Royal Hospital for Children and Women, Waterloo road—A case of transperitoneal nephrectomy for small round celled sarcoma in a boy, aged four years (under the care of Dr C O Hawthorne and Mr H J Curtis), 1319
Royal Infirmary, Newcastle on Tyne—A case of pneumococcal arthritis (under the care of Dr. G R Murray), 1604—Two rare cases of intussusception (under the care of Mr J Rutherford Morison), 1689
Royal Isle of Wight County Hospital—A case of traumatic tetanus, recovery, (under the care of Mr F J Wadham) 303
Royal Naval Hospital, Plymouth—A case of multiple abscesses in the liver secondary to perforating ulcer of the stomach (under the care of Staff Surgeon Edward R D Lasken, R N.), 1535
Royal Portsmouth Hospital—A case of traumatic dislocation of the hip in a boy, aged six years (under the care of Dr A Lloyd Owen) 954
Royal Southern Hospital, Liverpool.—A case of perforated gall bladder simulating perforated gastric ulcer (under the care of Mr G P Newbolt), 1534
St. George's Hospital.—Two cases of gastric surgery (under the care of Mr Herbert W. Allingham), 590—A case of perforated duodenal ulcer, operation, recovery (under the care of Dr Cyril Ogle and Mr. A Marmaduke Sheild), 890—Two cases of Intestinal Obstruction (under the care of Mr. G R Turner), 1035—An unusual case of intussusception, operation, recovery (under the care of Mr H S Pendlebury), 1766
St. Mary's Hospital—A case of traumatic rupture of the prostatic urethra, compound fracture of both legs, operation; recovery (under the care of Mr Edmund Owen), 443—Three cases of operation for suspected stone in the kidney, with clinical remarks (under the care of Mr. Edmund Owen), 1105
Seamen's Hospital, Funchal, Madeira—A case of double compound fracture of the tibia with simple fracture of the fibula untreated for one month, operation, recovery with sound limb (under the care of Mr. J. Geddes Scott), 1834
South Devon and East Cornwall Hospital—Three cases of grave abdominal injury showing the difficulty of forming a correct diagnosis (under the care of Mr. C. E Russel Rendle), 159—Two cases of perforating gastric ulcer occurring in sisters; operation, recovery (under the care of Mr. R H Lucy and Mr Whipple), 444—Case of perforated duodenal ulcer, cœliotomy, recovery (under the care of Mr. R H Lucy), 1466
Station Family Hospital, Rawal Pindi—A case of carcinoma of the rectum, operation (under the care of Captain T H. Goodwin R A M C) 666
Victoria Hospital, Folkestone—A case of acute intestinal obstruction due to embolism of branches of the superior mesenteric artery (under the care of Dr W J Tyson and Mr. W. W. Linington) 1248
Westminster Hospital.—A case of ulcus *carcinomatosum of the pylorus (under the* care of Dr. W Murrell) 514—A case of amputation through the thigh in a chronic diabetic who had necrosis of the foot, followed by a disappearance of the glycosuria (under the care of Mr. W G Spencer), 814—A case of acute Banti's disease (under the care of Dr. W Murrell), 1177—A case of cirrhosis of the liver treated surgically by the establishment of a collateral circulation (under the care of Dr W Murrell), 1602

# LIST OF ILLUSTRATIONS.

Photoprint and Two Diagrams accompanying a paper on Phantom Tumours (Sir W. H. Bennett, K C.V.O ), 1, 2, 4

Photoprints of Knee joints illustrating a lecture on So-called "*Internal Derangement of the Knee joint*" (Mr. A. E. J. Barker), 7, 8

Photoprints of Uteri illustrating paper on Abdominal Panhysterectomy (Dr. A. H. N Lewers), 15, 16

aving of Gravid Uterus Deformed by Fibroids (Mr. J. Bland-Sutton), 17

Diagrams and Two Photoprints illustrating paper on Beef Worm in the Orbital Cavity (Mr. T. W F. Gann), 20

oduction of a Photograph of Coins recovered from a Patient's Stomach (Lieut Col. G. W. P. Dennys), 24

l and Aural Wool-carrying Forceps (Dr. A. Stanley Green), 36

Photoprints of Hands illustrating paper on Volkmann's Contracture (Mr. L S Dudgeon), 78, 79

Photoprints accompanying paper on Nævus Verrucosus (Dr. H. Taylor), 87

oprint of an Occipital Meningocele (Mr. J. Lynn Thomas, C B ), 88

r bag for Clover's Inhaler (Dr. R. W. Lloyd), 99

hotographic Prints showing Curvature of Spine and Condition of Feet in Patients suffering from Friedreich's Ataxia (Dr. Guthrie Rankin), 151, 152

oprint showing Fibroma of the Breast in a Male Egyptian (Mr. A Webb Jones), 158

Charts showing respectively Mean Pulse and Mean Temperature in 80 Cases of Abdominal Section, illustrating a paper on the Progress of Surgical Methods (Dr. T B Grimsdale) 212, 213

Views of Dissected Hip joint with Ruptured Muscles and one View of the Hip joint from the inside illustrating a case of Traumatic Perineal Dislocation of the Right Hip (Mr. H. M. Rigby) 220, 221, 222

ral Botanical Drawings of Cassia Beareans, showing Inflorescence, Leaf, Pod, and Seed (Dr. D R O Sullivan Beare), 284, 285

Illustrations showing Apparatus for the use of Ultra violet Light in Skin Diseases (Dr. Hugh Walsham), 286, 287

Photoprints of casts, full face view and profile, of Czolgosz, the anarchist, 291

roved Vaccination Shield (Mr. Haydn Brown), 317

strations of a Portable Disinfector for Private and Hospital Use (Mr. Herbert J. Robson), 317

Diagrams showing Area of Dulness and Size and Position of Tumour in a case of Abdominal Tumour with Ascites (Dr. Thomas Watts Eden), 349, 350

Illustrations showing Flexion of Wrist and Hyper extension of Metacarpo-phalangeal Joints in two cases of Volkmann's Contracture, 373

dscape showing the position of the Torquay Destructor Chimney (The Sanitary Commissioner of THE LANCET), 405

Portraits of Patients, two Diagrams and four Views of Jaws, numerous Diagrams showing Clefts, Flaps, Instruments, Position of Patients, &c, illustrating a paper on Cleft Palate (Mr W. Arbuthnot Lane), 433, 434, 435, 436, 437, 500, 501, 502, 503

roscope Field showing Spindle celled Sarcoma of the Vagina (Dr. H. Macnaughton Jones), 440

o Diagrams accompanying a paper on the General Pathology of Tumours (Dr. C Powell White), 491, 492

p showing Position of Small pox Hospital Ships in the Thames in relation to Purfleet and West Thurrock, and a Wind Rose showing Prevalence of South-westerly Winds (Dr. J. C. Thresh), 496, 497

o Views of a case of Hydatid Disease of the Gall bladder (Mr Lawrie Hugh McGavin), 505

Illustrations of Semilunar Cartilages accompanying paper on 15 cases of Operation for Internal Derangement of the Knee joint (Mr. J. M. Cotterill), 511

proved Form of Vaccinator (Mr. M. H. C Palmer), 531

looping Nasal Polypus Snare (Dr. Atwood Thorne), 531

ree Microscope Fields showing Sections of Testis removed from Inguinal Canal, and other Illustrations accompanying the Hunterian Lectures on the Anatomy, Physiology, and Pathology of the Imperfectly Descended Testis (Mr. W. McAdam Eccles), 569, 571, 572, 573, 574, 576

Three Heads and One Diagram illustrating a paper on Grey Hair and Emotional States (Dr. Robert Jones), 584

Two Illustrations showing Tumour and Under Surface of Liver and Adjacent Parts accompanying a paper on Sarcomatous Tumour of the Tail of the Pancreas (Mr. J. D Malcolm), 587

Bossi s Instrument for Rapid Dilatation of the Os and Cervix Uteri, 594

Improved Clinical Thermometer, 603

Duck bill Speculum for Female Urethra (Mr. C. J. Wright), 603

Two Diagrams illustrating Lecture on the Blood vessels of Mamma's in Relation to those of Man (Mr. F. G. Parsons), 651

A Complete Obstetric and Gynæcological Outfit (Dr. Ralph Vincent), 677

Photographs of Patient before and after Operation for Spina Bifida (Mr. G L St George), 740

The Cortland Broughamette, 755

Sagittal Section of the Medulla, Pons, and Cerebellum accompanying description of a case of Primary Hæmorrhage into the Fourth Ventricle (Dr H W Reynolds), 813

Two *Illustrations showing Eruption on Extensor Surface of Elbow and* on the Flexor Surfaces of the Knees in a Case of Psoriasis Rupioides (Dr F Buszard), 815

Faradimeter (Dr. Samuel Sloan), 830

Two Charts showing Phagocytic Ratios of Blood in Cases of Furunculosis, Sycosis, and Acne (Prof. A. E. Wright), 878, 882

Two Photoprints showing Burmese Woman and her Son affected with Universal Hirsuteness (Dr A. J. Balmanno Squire), 887

New Deep Suture (Mr. S L. Woolmer), 889

Diagram of a Tooth lodged in the Intestine (Dr. G. Warnes), 921

Sectional view of a Pond and a Well accompanying paper on Typhoid Fever (Dr. W H. Corfield), 949

A Water Valve, 975

Four Sketches illustrating paper on Chronic Glaucoma, 984, 985

Four Perimeter Charts described in paper on Abiotrophy (Sir W. R Gowers), 1006

Temperature Chart accompanying paper on Pneumococcic Gastritis (Mr. A. G. R Foulerton), 1027

Illustration of a Set of Trocars and Cannulæ for Empyema (Mr. Wm. Turner), 1044

Two Sections of the Heart illustrating paper on Cardiac Inadequacy (Dr Alexander Morison), 1099

Illustration accompanying a paper on Carcinoma of the Ampulla of Vater (Dr F de Havilland Hall), 1103

Tracheotomy Instruments (Dr J C Garratt), 1120

A New Vaccination Pad, 1120

Figures of an Old Goitre and of a Solid Adenoma of the Thyroid illustrating paper on the Diagnosis and Treatment of the Various Forms of Goitre (Mr James Berry), 1227, 1228

Microphotograph of Crystals of Monohydric Magnesium Phosphate in Urine (Dr. T R Bradshaw), 1242

*Two Illustrations accompanying paper on a case of Acute Intestinal* Obstruction due to Embolism of Branches of the Superior Mesenteric Artery (Dr W J. Tyson and Mr W W. Linington), 1248, 1249

Forceps for Introduction of Drainage tubes (Mr. T. Garrett Horder), 1260

Six Photoprints of Fire grates and Several Charts and other Illustrations accompanying paper on Tests of Domestic Open Fire grates, 1343, 1344, 1345, 1346, 1347, 1348, 1350

One Nasal Syringe and two Nasal Douches (Dr. Wyatt Wingrave), 1375

Two Views of an Apparatus for Storing Liquid Air to illustrate a paper on Liquid Air as a Freezing Medium in the Laboratory (Dr. W. H. B Stoddart), 1385

New Aseptic Vaccinator (Dr John Wilson), 1408

New Clamp for Abdominal Operations (Dr. Bertram C. Stevens), 1408

Three Surgical Instruments for Use in Operation for Radical Cure of Inguinal Hernia (Prof. Tansini), 1464. Fig 1 ought to have been described as a retractor and Fig 2 as a hook for the spermatic cord.

Portrait of the late Dr. William Miller Ord, 1495

[*List of Illustrations continued on next page.*

## LIST OF ILLUSTRATIONS—(*Continued*).

Four Diagrams, one being an Embryo, illustrating paper on the Congenital Factor in Hernia (Mr. R. Hamilton Russell), 1520, 1521, 1522

An Eye Speculum (Mr. W. Lang), 1545

A New Anæsthetic Inhaler (Dr. A. Waring), 1545

A Porthole Ventilator accompanying a paper on the Ventilation of Ships (Staff-Surgeon W. E. Home), 1598

Figure showing the Fauces in Primary Gangrene of the Tonsils (Dr. Robert Fullerton), 1600

A Stereoscope for X-ray Work (Mr. Stephen Mayou), 1609

Three Charts accompanying paper on the Annual Variation of Puerperal Fever compared with that of Some Allied Diseases (Dr. A. L. Galabin), 1672, 1673

Four Diagrams illustrating Intussusception (Mr. J. Rutherford Morison) 1689, 1690

Temperature Chart in a case of Difficult Diagnosis with Rare C plication (Dr. H. J. Mackay), 1762

An Inhaler for giving Mixtures of Ether and Chloroform (Dr. F. Milward), 1779

Lithotomy Straps (Mr. C. Hamilton Whiteford), 1780

Calculi in Pouch of Bladder behind Prostate and Numerous Specim of Calculi (Mr. Reginald Harrison), 1821, 1822

Drawings showing Operation for the Fixation of Moveable Kidney ( T. Carwardine), 1823

Naso-pharyngeal Tube for Prolonged Nitrous Oxide Anæsthesia ( Harvey Hilliard), 1824

Eight Heads of Patients accompanying paper on Treatment of C genital Torticollis (Mr. Noble Smith), 1830, 1831, 1832

Three Drawings of New Clamp for keeping in Apposition the Edges Surgical Incisions (Mr. Haydn Brown), 1839

St. Martin-in-the-Fields, Westminster, in the County of London.—Saturday, July 5th, 1902.

# A Lecture

ON

# THE CAUSES AND SIGNIFICANCE OF PHANTOM TUMOURS.

*Delivered at St. George's Hospital*

y Sir WILLIAM H. BENNETT, K.C.V.O., F.R.C.S. Eng.,

ENIOR SURGEON TO THE HOSPITAL; MEMBER OF THE COURT OF EXAMINERS, ROYAL COLLEGE OF SURGEONS OF ENGLAND, ETC.

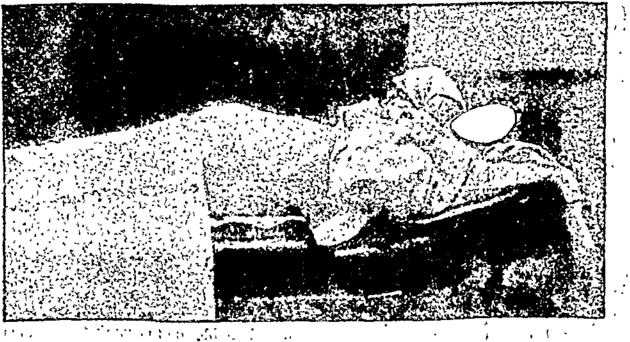
---

GENTLEMEN,—Phantoms, whatever their kind may be, ve a certain fascination for the majority of us, even if we e not superstitious. The very word recalls an early time of o when ghosts and other unpleasant things appealed ther strongly to the imagination; moreover, many of us ve, later in life, to face phantoms of some sort more often rhaps than we quite care to admit.

To-day I wish to call your attention to a surgical phantom" which differs from the phantoms of our youth, asmuch as it is not only visible but palpable—it can be en and handled. It is what is commonly known as a phantom tumour." This tumour comes and goes often thout obvious reason and generally without method; it is, a rule, painless, but sometimes it is the cause of great scomfort. The tumour is the result of muscular conaction; it is not in itself a disease, but it is a gn pointing to the existence of abnormal conditions which ay be close by or which may be somewhat remote. The aracteristics of these tumours are very uniform: they are ard and resistant, smooth, and in shape they conform to at of the muscle, or groups of muscles, concerned; over e abdomen they are always resonant, but less so than the rrounding parietes. Sometimes they disappear during eep, sometimes they do not; profound anæsthesia always ds to their disappearance. As I have already said, pain the tumour is generally conspicuous by its absence—the verse of what happens in muscular contractions occurring cramp; and it is a little difficult to understand how muslar contraction like that producing a phantom tumour can as a rule, so painless, although the contraction may in me cases persist, with certain intervals, for weeks or nths, or even longer. The fact, however, is undeniable. e causes of these tumours may be classified in the followg way: 1. Irritation.—(*a*) Irritation of the skin or of er superficial parts either immediately over the muscle muscles concerned or over the course of the nerves hich supply them; (*b*) the existence of underlying disease abnormality—for an example, supposing the tumour to be in the abdominal wall, some disease in the abdominal cavity which, by reason of its situation or relation, causes *nerve* irritation leading to contraction of a corresponding muscular area (such tumours, when occurring immediately over the underlying disease, are usually "protective"). 2. *Occupation.—In a certain number of cases* in which the occupation of the individual entails the use of a particular muscle or group of muscles for a long period continuously the muscles concerned come, as it were, into permanent action, and remain hard and enlarged, although the occupation has been temporarily discontinued. These are "occupation" phantoms." 3. Imitation.—In a certain type of neurotic people the tendency to imitate the diseases or deformities of others is very strong. "Nervous mimicry of disease" was the admirable term applied to these cases by Sir James Paget. The nervous mimicry of hip-disease is, perhaps, one of the commonest examples with which we meet of this curious tendency. Tumours are sometimes imitated in the same way, although the scope for the deception is necessarily very limited. These are "imitative phantoms."

Let me now give you a clinical example of each of these types.

FIG. 1.



Abdominal phantom simulating pregnancy, the result of irritation about the umbilicus (Case 1). From a photograph by Mr. Drake-Brockman.

### IRRITATION PHANTOMS.

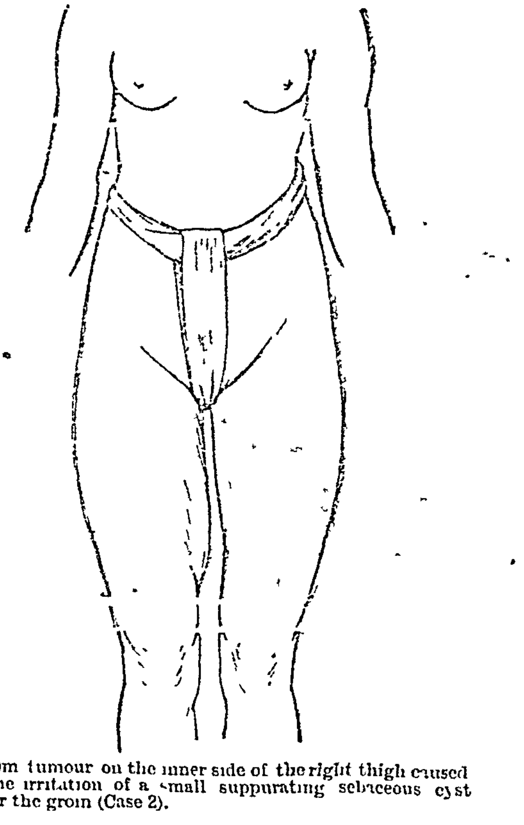
*Superficial Irritation.*—CASE 1.—About six months ago there was admitted into St. George's Hospital under my care a girl, 16 years of age, who presented all the appearances of being the subject of a large abdominal tumour below the umbilicus, and the suggestion had been seriously made that she was pregnant—a fact which shows how important a matter the proper appreciation of a thing of this kind may be. Upon examining the patient as she lay flat on her back the lower segment of the abdomen was exactly of the size and shape of that of a woman seven months pregnant, and nothing more characteristic in the way of outline could have been imagined (Fig. 1). The swelling, however, was resonant, and nothing could be grasped in the way of a tumour inside the abdomen either by the examination of the anterior abdominal region or by bimanual examination per rectum. The affected area of the anterior abdominal parietes, however, could be felt as a rounded, tense swelling very distinctly. The only other obvious abnormality was an area of acute eczema about the lower border of the navel. Bearing in mind what I have just said—viz., that the tumour was resonant and that no mass or disease of any kind inside the abdomen could be detected—I came to the conclusion that the case was one of phantom tumour due to the irritation of the patch of eczema, although, as sometimes happens, the tumour in this case persisted during sleep. The patient was placed under an anæsthetic, and as profound anæsthesia supervened the tumour could be felt to melt away under the hand, *leaving the abdominal outline normal.* A few hours afterwards, the patient having recovered from the effects of the anæsthetic, the tumour had returned in the *same shape and* situation as before. The obvious indication

No. 4088.

was to cure the eczema; this was, as so often happens, by no means easy, but finally little or no eczema was left, and the tumour was not noticeable. Later, however, the patient returned to the hospital with the eczema rather worse than before, the tumour being somewhat larger than it was when she first came under observation

CASE 2.—A well-nourished woman, 34 years old, consulted me on account of a swelling along the inner aspect of the right thigh, mainly over the adductor muscles, the shape of which it seemed somewhat to take. The history was one of a slight injury following upon a slip, which caused her to fall rather heavily, a year previously. Some bruising followed and a "bleb" (?) burst high up at the point at which the thigh joins the groin. This gave some trouble and was very slow in healing, as "matter formed." Three months after the injury the swelling of the thigh was first noticed on rising one morning; it was then large and was thought to have come suddenly; neither tenderness nor pain had, as a rule, been felt excepting after much exertion—e g., a longer walk than usual—when a feeling of great tiredness, stiffness, and aching pain occurred in the swelling which became temporarily larger and harder. The patient was well nourished and presented no appearance of serious disease. Upon examination the inner side of the right thigh was occupied by an elongated swelling along the adductor area extending above to within two inches of the pubic spine; it was hard, elastic, slightly moveable laterally, and seemed to involve the adductor longus muscle, extending downwards along the adductor magnus nearly to its lower end (Fig 2). A skiagram showed a slightly stronger shadow over the area of the tumour than over the other soft parts. As the peculiar elasticity raised a suspicion of fluid deeply seated several punctures with an exploring syringe were made with, however, a purely negative result, a little normal blood and nothing more coming away. As neither rest nor medicinal means affected the tumour in any degree whatever an exploratory incision was decided upon. The thigh was therefore packed in the usual way preparatory to operation and an anæsthetic was administered. Upon removing the packing and exposing the thigh the tumour had entirely disappeared. I confess that at the moment I was entirely at a loss to explain the disappearance of the swelling, but having in my mind the suspicion of fluctuation which existed I thought that the disappearance might perhaps be accounted for by the bursting of some deep thin-walled cyst whilst the patient was being lifted from her bed on to the operating table after the administration of the anæsthetic, although the disappearance seemed really to be too complete to be accounted for in this way. At any rate, nothing in the way of an exploratory operation was justifiable, and the patient was returned to her bed, nothing having been done. Upon seeing her again later in the day after she had recovered from the anæsthetic the tumour was as large and as manifest as usual. The diagnosis of the tumour as a phantom followed as a matter of course, but no source of irritation could be found excepting the remains of a small sebaceous cyst not quite healed in the vulvo-femoral chink. A little later this sebaceous residuum gave some trouble and was removed. Up to the time of the removal of this remnant of the sebaceous cyst the tumour had remained unchanged, but after the small operation necessary the tumour disappeared spontaneously and four months later had shown no sign of recurrence.

FIG 2.



Phantom tumour on the inner side of the right thigh caused by the irritation of a small suppurating sebaceous cyst under the groin (Case 2).

There can, I suppose, be no doubt that in this case the irritation of the sebaceous cyst gave the necessary stimulus for the production of the muscle tumour. The case is the most interesting of its kind with which I have met.

*Deep irritation.*—CASE 3.—A woman, 45 years old, had suffered for three years occasionally from vague abdominal pains; these, although somewhat diffused generally over the whole abdomen, were as a rule concentrated over the left hypochondriac and lumbar regions. On two occasions there had been very severe attacks of pain accompanied by vomiting with high temperature and on each of these occasions considerable swelling over the region of the cæcum had shown itself, subsiding slowly as the pains disappeared. On one occasion she had been jaundiced for nearly a week, but of this she thought nothing, as she had when quite young, had several attacks of jaundice. I first saw her at a time when the pains were worse than usual and confined to the right side of the abdomen. They were not acute enough to cause great distress, but there was some nausea and a slightly raised temperature (100° F.). Upon examining the abdomen the right side moved less freely than the left and over the cæcum was a well-marked swelling a little less resonant than the surrounding area, precisely like that seen in certain cases of appendicitis. There was, however, no great tenderness except at McBurney's point, where moderate pressure elicited acute pain which shot upwards, the swelling at the same time becoming more tense and hard. No other objective abnormality could be detected, but pressure just below the ninth costal cartilage caused the patient to "flinch." The motions were pale but not without bile, and the urine contained a faint trace of albumin. The patient looked ill, was losing flesh, and was clearly the subject of disease of some importance. Upon the subsidence of this slight exacerbation I thought that there was a suggestion of yellowishness about the conjunctivæ but it was too faint to be of consequence The diagnosis was clearly doubtful, but it seemed to lay between appendicitis and gall-bladder trouble It was manifest, however, that surgical interference was necessary, and I therefore opened the abdomen by an incision which would enable me to examine the appendix and gall-bladder. The appendix and the parts about it were perfectly normal. the gall-bladder was contracted, connected by inflammatory adhesions to the liver and duodenum, and contained a small pyramidal stone impacted in its duct The stone was removed (the gall-bladder having first been freed from adhesions), the opening was sewn up, and the abdominal wound closed by fish-gut, sutures in the ordinary way. A severe attack of jaundice supervened upon the operation and was slow in subsiding although it ultimately disappeared. The patient recovered from the operation without any drawback and six months later was perfectly well in all respects. The swelling over the cæcal region never became manifest after the operation.

This case is interesting inasmuch as it shows how very misleading a phantom may be when it is remote from the irritation which gives rise to it, and it is further of interest as it, together with the next case, shows the fallacy of trusting to tenderness over McBurney's point as a sure sign of appendix disease.

### PROTECTIVE PHANTOMS.

These are irritation phantoms, but they differ from those just described, inasmuch as the phantom immediately overlies and conceals the true disease beneath—"protective" is therefore a convenient name by which to describe them, as they protect the underlying condition from pressure, &c. They are practically confined to the abdominal wall.

CASE 4.—A young married woman, three months pregnant, was admitted into Wright's Ward under my care about 18 months ago on account of what was said to be appendicitis. It was the first attack of the kind from which she had suffered, and the history, although somewhat vague, seemed to point to the disease referred to. Upon examining the abdomen there was found a very distinct globular tumour in the right iliac region such as is frequently seen in appendicitis. The tumour was resonant but slightly less so than the surrounding parietes; "sub-resonant" would be a fair description of the result obtained by percussion. There was general pain over the lower abdominal region and some tenderness concentrated over McBurney's point; no deep pressure was tolerable, as the tenderness was so acute. The temperature was high (104° F.), a rigor was said to have occurred, and the patient was apparently in a serious condition. My impression was that the case was not one of appendicitis, but still on the whole I thought it better to operate as if for that disease. The patient was therefore anæsthetised in the usual way and upon removing the antiseptic packings the tumour was found to have entirely disappeared. This confirmed me in my impression that the case was not one of appendicitis, for although in certain cases of appendix disease *some* of the obvious swelling is of the phantom kind and disappears under profound anæsthesia I have never in appendicitis seen the *whole* of the swelling disappear. I felt pretty sure that the objective swelling was a "phantom" connected with some pelvic disease, although nothing abnormal could be felt on palpation either through the abdominal wall or per vaginam. I operated as if for appendicitis and found the appendix and cæcum quite normal. Upon examining the right ovary it was a little enlarged, bright red in colour, with several white patches scattered over its surface; on pricking one of these a drop of pus came away. The ovary was removed in the usual manner and the abdominal wound was closed. The patient recovered rapidly and was up and about in a fortnight. The ovary when it was examined after its removal was found to be in a condition of acute inflammation with spots of commencing suppuration scattered throughout its substance.

Acute suppurative ovaritis during early pregnancy is rare, but some cases have been recorded.

The commonest protective phantom is probably that which occurs in certain conditions of the liver, and is of a good deal of importance as it is more commonly mistaken for hepatic abscess than is generally supposed. The next case provides an example.

CASE 5.—A soldier, 38 years old, was invalided from South Africa with disease of the liver, the history and signs of which pointed strongly to abscess, and immediately upon landing (April 23rd, 1901) he came under my care with a view to immediate operation. He was a colonial who had been in South Africa from the beginning of the war and had remained well until nine months before he arrived in this country. The illness commenced apparently with an attack of dysentery of a mild type. After this he never felt well; he had frequent attacks of "fever" (?malarial) with rigors and rapid loss of flesh. For six months there had been constant pain about the liver, sometimes better, sometimes worse. For about the same time there had been tenderness, sometimes extreme, below the ribs on the right side. For two months there had been jaundice which for a fortnight had been intense. Upon coming under observation the patient was greatly emaciated and looked very ill. The skin and conjunctivæ were of a deep yellow tint, and the motions were void of bile, which was present in the urine in great quantity. The temperature ranged from 101° F. in the morning to 104·5° at night. Two-thirds of the abdominal cavity was occupied apparently by a very large liver which on the right side reached to within one inch of the iliac spine; it was generally smooth except at a point which corresponded to the upper segment of the right rectus muscle where a prominent tumour bulged forwards. This tumour was dull and elastic and upon very gentle pressure was extremely painful; moreover, upon pressure the bulging part became harder to the touch. There was some general tenderness over the whole of the large liver, but only of a moderate degree. By some who felt it the bulging portion seemed to fluctuate, but of this I could not satisfy myself. An abdominal exploration was clearly indicated, so the patient was prepared for operation in the usual way and the anæsthetic was administered on the bed, the patient being afterwards lifted on to the operating table. Upon removing the antiseptic packing it was seen that the bulging portion of the tumour had entirely gone and that the enlarged liver presented a uniformly smooth surface. I concluded at once that the tumour was a phantom, but as there was a possibility that its disappearance may have been due to the bursting of an abscess I opened the abdomen through the site of the previously bulging part. No abscess or inequality of the large liver existed and its surface was perfectly smooth. I have never seen so large a liver exposed by operation; it seemed to occupy the best part of the abdominal cavity, the intestines being pushed down to a small space in the left iliac region. On the surface it was rather darker in colour than normal; to the touch it was very hard. It was punctured in all directions by a long trocar and cannula, but nothing but blood came away. In all, 14 punctures were made. Free hæmorrhage followed each puncture but stopped spontaneously. The abdominal wound was closed by fish-gut sutures and one grain of calomel night and morning was prescribed. The patient recovered rapidly from the operation. The temperature became normal at the end of 10 days, and on August 18th, when last seen, the patient was apparently well. All jaundice had gone, he had gained nearly two stones in weight, and the liver, almost of normal shape, extended only two inches below the ribs. The bulging area in this case was clearly a "phantom" in the rectus muscle.

The case was remarkable in many respects, but the only point which I wish to emphasise here is the way in which the bulging phantom simulated the coming forward of an hepatic abscess. As I have already said, these supra-hepatic phantom tumours are of much more importance in relation to the diagnosis of liver abscess than is commonly supposed.

### OCCUPATION PHANTOMS.

These are unusual, and their diagnosis is not always easy. The following case affords a remarkable example.

CASE 6.—A man, whom most of you must well remember, was admitted under my care a short time since into the Fitzwilliam Ward; he was a compositor, 35 years of age, a very spare and sober man. Two months before his admission, as he was suffering from a bad cough, which he had been told was due to consumption, he applied for treatment at the Brompton Hospital for Consumption, and was there told that nothing of consequence was wrong in his chest, but his attention was called to a tumour above the left clavicle, of the existence of which he was previously quite ignorant. Now, it so happened that his wife was the subject of carcinoma of the breast of a most painful kind, and the discovery of the tumour came upon him as a considerable shock, mainly by reason of his wife's condition, which led him to think that he might be suffering from a cancer. The patient's thoughts now became concentrated upon this tumour with the result that first it became painful and then that it steadily grew—at least, that was his firm conviction. He consequently came to St. George's Hospital for advice and treatment. Upon examination there was occupying the left subclavian region a very distinct tumour which to the touch was as hard as bone; it was not tender, but a constant aching pain was complained of which at times shot down the arm like a "sharp toothache" (Fig. 3). Taking into consideration the health of the man and the feel of the mass the first impression naturally was, especially as the subclavian artery was very high in situation, that the swelling was due to the growth of an exostosis or to the existence of a "cervical rib" A skiagram, however, showed nothing whatever abnormal about the bony parts, nor did it show anything suggestive of sarcoma. A further inquiry into the man's history at this stage elicited the following interesting facts. In the course of his work as a compositor the patient was in the habit of holding in his left hand daily, and often for hours together, a "stick" which held the type which he was using, and he stated that for some time he had become unusually tired about the shoulder whilst at work, and he knew that when he was tired he was in the habit of holding the shoulder very high, as the change of position relieved him temporarily to some extent. The man's anxiety was so great that nothing short of an operation of some kind would satisfy him, so after he had been prepared in the usual way he was anæsthetised with a view to operation, although, as I was fortunate enough to say at the time, I should not have been surprised diseases. It acts both by its influence on digestion and by causing cutaneous hyperæmia. It does least harm when taken with food and when the percentage of alcohol present is small. On the whole the lighter wines are less prejudicial in their effects than other forms of alcohol, but spirits (except when well diluted), champagne, and beer should be avoided. Tea frequently does much harm, chiefly because it is taken in excess and apart from food; it is also often infused too long. Coffee and cocoa are less injurious, but these, too, should be taken in moderation.

I may mention now the influence of tobacco. The connexion between disease of the skin and tobacco is not so obvious as in the case of alcohol, but I have little doubt of the harmful effect of tobacco, especially in excess; caution on the part of the patient in this respect is therefore advisable.

There are, however, other ingesta deserving notice, as they can give rise to disease of the skin. These are drugs. Many medicines have the power of evoking skin manifestations even in those who are in health, and still more likely is the skin to be affected in disease, so that the possibility of some part of the lesion being the result of medication must always be borne in mind.

The climate and air have much influence on many diseases of the skin. On the whole, a fairly dry inland situation is best for these cases, for sea air is very irritating in many forms of eczema; but for conditions in which the general nutrition is impaired, as in lupus, sea air may have a markedly beneficial effect. It is difficult to lay down general rules on the subject and each case must be treated on its merits.

The effect on cutaneous disease of soap and water is so important as to require special mention. Even in health frequent washing damages the skin by depriving it of much or all of its natural fat, so that it becomes unnaturally dry and also probably more easily invaded by parasitic micro-organisms. The effect is still more harmful in disease. Except in the skin diseases due to the animal and some of the vegetable parasites washing is of no therapeutic value, and in many morbid cutaneous conditions, especially in eczema, it may be exceedingly harmful. Where washing cannot be avoided the injurious effect of the water may be to some extent mitigated by the addition to it of oatmeal or gelatin, so that a demulcent action is exerted on the skin. In cases in which washing is admissible the choice of a soap is generally not difficult. That soap is beneficial to the individual patient the use of which is not followed by redness or smarting. It is hardly necessary to say that there is no soap that far surpasses all others. Of recent years superfatted soaps have been introduced, and they are certainly less irritating to most skins; they are not, however, so pleasant to use, and naturally their detergent effect is less. Of medicated soaps I have little to say, as I do not consider soap to be a convenient vehicle for the application of drugs except in very peculiar cases.

We now come to the more directly therapeutic part of the subject. It is obvious that if the general health be impaired we should endeavour to restore it, although we may be unable to recognise that any causal connexion exists between the general condition and the cutaneous lesion. The digestion should be treated if dyspepsia be present, and any abnormal condition of the bowels, such as constipation or diarrhœa, should be corrected. In many cases, however, the general health appears to be perfect.

There is a very definite opinion prevalent amongst the public and held even by some medical men that there is some risk in curing a disease of the skin. The eruption and the discharge from it are imagined to be beneficial and it is thought that if these are removed then the disease is "driven inwards" and produces very serious symptoms. These ideas were formerly very widespread among the medical profession and they are to be found in all the older works on dermatology. Yet at the present time it cannot be said that we have any definite facts to support such an opinion. It is known that in some of the specific fevers, if the rash does not come out well, or if it recedes, the constitutional symptoms tend to be more severe and a fatal result often follows. This is probably the foundation or part of the foundation for the idea that the rapid removal of a cutaneous malady may give rise to severe internal disease. Possibly since the skin is a great excretory organ the cessation of its secretion may cause the retention in the body of noxious substances, but of this we know very little. At all events, no apprehension of doing harm to the patient need deter us from removing as speedily as possible a disease of the skin.

An accurate diagnosis is the first essential for the satisfactory treatment of skin diseases, as of disease in any other part of the body. Our aim in treatment should be to remove the cause of the disease, if possible; but if the cause is unknown or if it cannot be removed we must treat the symptoms, and even when the cause is known and the disease is readily amenable to treatment the symptoms, or some of the symptoms, may need treatment, either because they are especially distressing to the patient or because it is not possible to remove the cause immediately. For instance, it is sometimes necessary to treat the itching of psoriasis because it may be very troublesome in itself, although we can in a few weeks or months completely remove the disease. It must not be imagined that when we know the cause the treatment which is the most obvious is necessarily the best. Many cutaneous diseases are now known to be microbic in origin, yet the direct application of antiseptics will in many cases not lead to recovery. Indirect methods are thus sometimes indicated.

The treatment of a disease of the skin may be internal or external. At one time the internal treatment was considered of very great importance in all forms of cutaneous disease, while external applications were thought to be of much less importance. On the whole the recent tendency has been to exalt the efficacy of external treatment and to discredit somewhat internal medication. It should be obvious from even a superficial study of the etiology of the diseases of the skin, even so far as we are acquainted with it, that in one disease internal treatment and in another external treatment must be of the most value, but in nearly all diseases of the skin both methods of treatment are desirable or even necessary.

Here seems to be the most convenient place to speak of the use of the natural mineral waters in dermatology. I think there can be no question that their value has been overrated. Doubtlessly in some cases the pure air, the simple diet, and the early hours observed at a spa contribute materially to the improvement of the condition of the skin, but it is improbable that the mineral waters themselves have any more than a very slight beneficial effect. Yet there is a very general opinion that these waters are of great efficacy, but disappointment will almost certainly follow any very exalted expectation of the benefit likely to result from their employment.

I have no intention of considering all the drugs which may be administered in cutaneous disease, but I think it well to say a few words on one of them—namely, arsenic. For many years arsenic has been looked upon as the special drug to be employed in many skin diseases, and, in fact, many medical men administer arsenic in almost every case of disease of the skin with which they have to deal. Yet, curiously, those who have most to do with the treatment of cutaneous disease employ the drug comparatively rarely—in fact, I am inclined to think that they employ it more rarely every year that goes by. Some 30 or 40 years ago a Mr. Thomas Hunt advocated the administration of arsenic in all skin diseases; he gave it very systematically and for very long periods, even for many years. This very prolonged use of arsenic is not common nowadays, yet at the recent Dermatological Congress in Breslau one speaker maintained that arsenic could not be said to have failed until it had been administered for several years. Arsenic is indeed of value, even of great value, in several cutaneous disorders, for instance, in psoriasis, pemphigus, and lichen planus, but its action is by no means certain; it is often slow in manifesting itself and the drug cannot or should not be given if the skin is distinctly inflamed, for it increases the inflammation and may cause the spread of the disease which it was intended to cure. Moreover, arsenic is capable of giving rise itself to morbid changes in the skin; not only does it increase, as I have said, any inflammation which is already present, but when the drug is administered for a prolonged period, even in small doses, the skin becomes pigmented, and on the palms and soles great thickening of the epidermis occurs, and in a few cases multiple epitheliomata have developed. Enough has been said to show that arsenic should not be given unnecessarily or hastily; indeed, as a rule arsenic should only be tried late in a disease, when other modes of treatment have failed. There is no other drug about which I think it necessary to speak in this connexion, for there is no other which has been so misused as arsenic.

With regard to the external remedies the dermatologist has an extensive choice. Baths are in certain cases of great value. In no other way is it possible to obtain so thorough an action on the skin, but, on the other hand, there is the risk of the absorption by the skin of substances from the bath, so that a bath should never contain any substance the absorption of which might be dangerous. "Permanent" baths, in which a patient is immersed for days or even weeks, are but little used in this country and though occasionally of great use they are troublesome and are of very limited application. The capacity of an ordinary bath is about 30 gallons, and the quantity of drug to be added must be calculated for that amount. Many modern baths, however, do not hold much more than 20 or 25 gallons, so that a little less medicament should be ordered.

Ointments are certainly more frequently prescribed than any other form of application, and they are very convenient, especially when inunction is required, but they are uncleanly and may often usefully be replaced by other applications. Ointments are usually at the present day made up with hard and soft paraffin. These keep well, never becoming rancid, and therefore do not tend to irritate even though they have been made long previously. This advantage does not appear to me to be of any great moment, for ointments are better for being freshly prepared, but the animal and vegetable fats seem to me to be *much better suited for ointment bases than the paraffins,* and I think that a drug made into an ointment with a basis of fat is able to exert a deeper effect on the skin It is important for you to bear in mind that ointments containing mercury and its salts must not be applied over too large an area as there is great risk of absorption. Ointments are not suited for any condition in which there is a large amount of exudation, for this exudation raises the ointment from the surface of the skin and to a great extent prevents it exerting its effect. When there is a profuse secretion from the skin lotions and dusting powders are suitable. When lotions are applied it is generally advisable to keep the part continuously moist, but no oil-silk should be applied over the dressing Dusting powders act chiefly by absorbing any exudation that may be present. They have to be used freely to obtain the best effect, and are hardly suited for patients who have to go about their work. Traumaticin, which is a solution of gutta-percha in chloroform, forms a very convenient vehicle for many drugs. When painted on the surface of the skin it dries quickly and forms an impermeable covering, which maintains the medicament in close contact with the part and at the same time effectually prevents any staining of the clothes Bassorin and gelanthum are two *very pleasant bases. They can be* smeared on the skin, and in a short time they dry and form a closely-adherent pellicle, which is, however, readily soluble in water, so they can be removed quickly. Unna's plaster muslins and salve muslins are useful vehicles when it is desired to obtain the prolonged action of a drug on a part. Pastes are also of value as they allow an exudation to make its way through them and they are therefore often superior to ointments. Pastes are practically composed of a combination of an ointment with a powder.

I need say but little of surgical treatment, scraping, excision, skin-grafting—all have their place in dermatological therapeutics—nor need I here describe the treatment of disease of the skin with light or the Roentgen rays; they are both of them of considerable value in suitable cases You will find that as the disease varies from time to time so will it be necessary to alter the drugs employed and the mode of their application.

Finally, I might suggest that to become well acquainted with the therapeutics of a few substances and the best mode of employing them will be better than to make a hasty inconclusive trial of every new preparation or treatment that is devised.

---

HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK.—In aid of the funds of this hospital there will be an amateur production of a new and original four-act play (for the first time in London) entitled *The Scarred Hand*, by Val de Garno and Leopold Montague, on Monday, Jan. 13th, at St George's Hall, Langham-place, W. We understand that the pen-name of Val de Garno veils more or less closely the identity of a member of the medical profession and that the play itself, which has had considerable success in the provinces, possesses a strong medical element.

# A Clinical Lecture

ON

# SEVENTEEN CASES OPERATED ON FOR SO-CALLED "INTERNAL DERANGEMENT OF THE KNEE-JOINT."

*Delivered at University College Hospital*

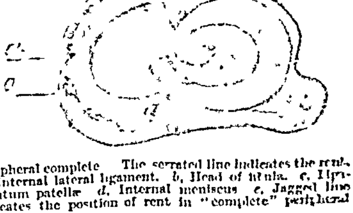
BY ARTHUR E. J. BARKER, F.R.C.S. ENG. AND IREL.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AT UNIVERSITY COLLEGE AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

GENTLEMEN,—It so happens that an interesting group of cases of "internal derangement of the knee-joint" has comparatively recently been operated on in my wards at University College Hospital. These are well deserving of study, helping us as they do to understand something of the pathology, clinical history, and treatment of this affection. But for any safe generalisation on these points we must take larger numbers To this end I have looked up the notes of all the cases which have fallen to my lot for operation within the past five years or so in hospital and added some seven on which I have operated in private during the same period All these, taken together, in which the joint has been opened are safer guides than others treated by palliative measures in which the structures involved have *not* been seen and in which the actual details of the lesions must accordingly remain to some extent doubtful. Of the latter, of course, one sees a much larger number; for it must be obvious at once to anyone who goes into the matter that all cases of "internal derangement of the knee-joint" do not require operation.

Now, first of all, what is meant by the title just employed, which was, I believe, first used by Mr. Hey of Leeds many years ago? Although the usual name now given to the condition described formerly as "internal derangement of the knee-joint" is "dislocation of the semilunar cartilage," it becomes quite clear to anyone who sees many cases of the lesion in open joints that there are several varieties of displacement, both as to position and degree, included under the term. It is important to bear this in mind, inasmuch as the same treatment is *not applicable to all. In order* to obtain some clear notion on these points let us glance at what has been actually seen when operating on the joints in this group of cases alluded to In the first place, the cartilage affected has been in every case the *internal.* And in the many other cases which I have seen but not operated on there has been clear evidence that the internal meniscus was the one at fault in all but one doubtful case This may be only a coincidence, but it is at least significant. The next point observed was that the semilunar cartilage was in all these cases split in the direction of its fibres, which run, as is well known, in a semicircle. In none of them was the cartilage torn across at any point between its two ends. Such lesions are said to occur, and I know of one most competent observer

FIG. 1.



"Peripheral complete The serrated line indicates the rent. *a*, Internal lateral ligament. *b*, Head of tibia. *c*, Ligamentum patellæ *d*, Internal meniscus *e*, Jagged line indicates the position of rent in "complete" peripheral separation.

"central splitting," also in cases where the "partial rent" s behind the internal lateral ligament. Here it is better to omplete the rent and to take away the whole meniscus.

It goes without saying that all these measures must be arried out without any manipulation of the parts involved vith the fingers. Nothing should touch the open surfaces xcept carefully sterilised metal instruments and sterile gauze. Antiseptics must be avoided They are calculated nly to increase the irritation in the joint. Moreover, the vound should not be kept open one moment longer than is bsolutely necessary. An ice bag over the dressings for the irst week or so is pleasant to the patient and probably keeps lown the effusion which usually follows to some slight extent he traumatic insult to the structures of the articulation. Treated on these lines there should be but little risk in these perations and all should heal well without trouble as these ave done.

*List of Cases of Internal Derangement of the Knee-joint.*

| No. | Sex. | Age. | Year. | Nature of derangement. |
|---|---|---|---|---|
| 1 | M. | 24 years. | 1895 | Partial anterior. |
| 2 | M. | 44 " | 1896 | Complete internal dislocation. |
| 3 | M. | 26 " | 1896 | " " " |
| 4 | M. | 33 " | 1896 | " " " |
| 5 | M. | 40 " | 1896 | Partial posterior. |
| 6 | M. | 21 " | 1897 | Complete internal dislocation. |
| 7 | M. | 26 " | — | Partial anterior. |
| 8 | M. | 29 " | 1898 | Polypoid tag. |
| 9 | M. | 40 " | 1898 | Partial anterior. |
| 10 | M. | 24 " | 1898 | Complete internal dislocation. |
| 11 | M. | 18 " | 1899 | Partial anterior. |
| 12 | M. | 19 " | 1900 | Central complete. |
| 13 | M. | 16 " | 1901 | " " |
| 14 | M. | 28 " | 1901 | Partial posterior. |
| 15 | M. | 21 " | — | Complete internal dislocation. |
| 16 | M. | 22 " | 1901 | — |
| 17 | M. | 32 " | 1901 | — |

These 17 cases are made up as follows: Complete internal dislocation, six (Fig. 5); partial anterior peripheral, 5 (Fig. 3); partial posterior peripheral. 3 (Fig. 4); central complete, 2 (Fig. 2); and polypoid tag. 1 (Fig. 6); total 17.

# ON THE ETIOLOGY AND PATHOLOGY OF SCURVY.

By GEORGE LAMB, M.B. Glasg.,
CAPTAIN, INDIAN MEDICAL SERVICE.

*(From the Research Laboratory, Bombay.)*

THE disease clinically designated as "scurvy"—that is, a collection of symptoms known to clinicians as scurvy or the scorbutic condition—has during the last few years received renewed attention from pathologists with the view of determining what is the pathological condition which underlies these symptoms and what is the cause of this pathological condition. Three hypotheses have recently been put forward by different observers. These hypotheses are founded for the most part on direct observations on cases of scurvy and on the result of experiments on animals. They may be briefly summarised as follows.

1. Professor A. E. Wright[1] of Netley in 1895 put forward the theory that the scorbutic condition was probably a condition of acid intoxication—that is, a condition in which there was a marked diminution in the normal alkalinity of the blood plasma, the result of a dietary of food-stuffs which contained a large excess of mineral acids over bases—a dietary, in fact, of meats, especially salted meat, and cereals, to the exclusion of green vegetables, tubers, and potatoes. This condition of acid intoxication he compared to the acid intoxication which can be experimentally produced in herbivora by the ingestion of a surplus of mineral acids. It is unnecessary for my purpose to follow Professor Wright through the close reasoning which runs through this communication. At a later date he was able to test the correctness of the inferences which he had previously set forth. Thus, in THE LANCET[2] he recently recorded the results of the estimation of the alkalinity of the blood serum in the case of seven soldiers who had been invalided from South Africa to Netley. These patients all presented the classical symptoms of scurvy, in most instances in a marked degree. In every case the alkalinity of the blood serum was found to be strikingly reduced below the normal. Not only was this the case, but a very striking amelioration of the condition followed upon the exhibition of lactate of soda and other similar substances. It would appear, therefore, from these facts, that Professor Wright had established beyond a doubt that scorbutic symptoms are, in some instances at least, associated with a condition of acid intoxication which can easily be rectified by the administration of salts of the vegetable acids. If this hypothesis could be supported by observations in India similar to his own the prophylaxis and treatment of this condition would become a simple matter. Scurvy, which is so commonly seen in Indian jails and which is such a frequent cause of invaliding during active service on the frontier of India, would soon become a thing of the past.

2. Lieutenant W. Glen Liston, I.M.S.,[3] investigated in the jail at Akola, Berar, four cases which showed marked scorbutic symptoms. In the fæces of all these patients he found the ova of ankylostoma duodenale in large numbers He therefore put forward the opinion that the symptoms noticed were in all probability dependent on the presence in large numbers of this intestinal parasite. It would further appear from Major Reilly's remarks[4] on Lieutenant Liston's observations that several cases of scurvy which were almost moribund were ultimately cured as soon as the parasites had been expelled from the intestine by the exhibition of thymol. Lieutenant Liston's description of the symptoms in these cases does not, to my mind, convey the idea that he was dealing with true cases of scurvy. A profound anæmia seems to have been the predominant condition. Further, it is apparent, in view of the great prevalence of this intestinal parasite in healthy natives of India, that these observations would have to be greatly extended before any definite conclusion could be arrived at.

3. Finally, Mr. F. G. Jackson and Dr. Vaughan Harley[5] have come to the conclusion that neither lime-juice nor fresh vegetables prevent scurvy or cure it. They consider that scurvy is a condition of ptomaine poisoning produced through the eating of tainted animal food. This opinion, which was first propounded by Professor Torup of Christiania, is advocated by Mr. Jackson and Dr. Harley as being in consonance both with the observations of sojourners in the Arctic and Antarctic regions and with the results of certain experiments on monkeys which were made by themselves. This last theory may at once be dismissed from consideration in connexion with the explanation of the scorbutic symptoms so commonly seen amongst the prisoners in Indian jails and amongst the sepoys and followers in native regiments when employed on field service on the frontier of India.

The symptoms of the disease as seen in these bodies of men are the ordinary and classical symptoms known as scurvy. There can therefore be no doubt as to the identity. from a clinical standpoint at least, of the ordinary scurvy and of scurvy as seen and described by numerous medical officers of the army of India. Now these men are for the most part cereal eaters. In jails the meat ration, as we shall see later, consists of four ounces of fresh meat without bone. This ration, as a rule, is given only once a week. Further. on field service the native army is not supplied with any tinned meat. The only meat ration which is issued is, as circumstances permit, the flesh of goats or sheep. Even this ration is, from caste prejudice, not taken advantage of by many men. From personal experience, moreover, I can say that many of those men who suffered from severe scurvy during the Waziristan expedition of 1894-95 never ate meat of any kind, confining themselves entirely to a cereal and vegetable dietary. Such, also, I know to be the common experience of other medical officers. It is apparent, therefore, that in the light of these facts the ptomaine theory of the etiology of scurvy will not explain the causation of this disease as it is commonly seen in India.

---

[1] Army Medical Report for the year 1895

[2] THE LANCET, August 25th, 1900, p. 565.

[3] Indian Medical Gazette, October, 1900. p. 330.

[4] Ibid., July, 1900, p. 268.

[5] THE LANCET, April 28th, 1900, p. 1134.

The observations in 11 cases of scurvy which I have now to put on record were made solely with the object of ascertaining if more evidence could be obtained in support of either of the hypotheses mentioned above (No. 1 and No. 2)—viz., the hypotheses put forward by Professor Wright and Lieutenant Liston respectively. In each case the alkalinity of the blood serum was estimated and the fæces were examined carefully for ova of dochmius duodenalis.

The method which was used to measure the alkalinity of the blood serum was the method which has been devised and described by Professor Wright.[6] I may mention in passing that I had the advantage of having been taught the technique of this method by Professor Wright himself and of having made many observations on animals and on man under his direct supervision. There can therefore be no doubt on the question of the comparability of my results from the point of view of the technique employed with those of Professor Wright. Dilutions of deci-normal sulphuric acid in multiples of 10, or when necessary of five, were employed in titrating the serum. I have to thank Major Collis-Barrie, I.M.S., chemical examiner to the Government of Bombay, for supplying me with the standard deci-normal acid solution. The dilutions of this were made with normal saline solution. The indicator employed was, as recommended by Professor Wright, a sensitive red litmus paper, for which also I am indebted to Major Collis-Barrie.

As a preliminary step I estimated, as controls, the alkalinity of several samples of blood serum taken from healthy natives, servants in this laboratory. I found that among these natives the maximum value of the alkalinity of the serum was $\frac{N}{25}$—that is, that the blood serum was exactly neutralised by an equal quantity of a 25-fold dilution of normal sulphuric acid. The average alkalinity was found to be equivalent to $\frac{N}{30}$ sulphuric acid. This result would appear to show that the alkalinity of the blood of natives of India is slightly greater than that of the blood of Europeans, for Professor Wright[6] has stated that on the average he found the normal alkalinity to be $\frac{N}{35}$. In conducting the examination of the fæces, undertaken to test the theory of Lieutenant Liston above referred to, slides were prepared either from the fresh fæces, when these were available, or from a sample which had been kept in a weak solution of carbolic acid. From three to six specimens were carefully examined in every case for the ova of ankylostoma.

I have first to detail the result of the examination conducted in the case of a series of five cases of scurvy occurring in prisoners in Thana Jail, an institution situated a few miles out of Bombay. I am indebted to Dr. Moos, the medical officer of this jail, for his kindness in bringing these cases under my notice and also in affording me every opportunity of investigating them.

CASE 1.—The patient was a Hindu of the Koli caste, aged 35 years, who had been admitted into the jail on Dec. 7th, 1899. The patient had enjoyed good health until just before his admission into the hospital. He was received into the hospital on Sept. 5th, 1900, complaining of pains in the legs and presenting symptoms which warranted a diagnosis of scurvy. He came under my observation on the 25th, when his condition was as follows: The gums were very much swollen; they were spongy and bled easily on being touched; the teeth were very loose. There was slight œdema of the face. Both legs below the knees were swollen, hard, and brawny in appearance; they were very painful on the slightest pressure. This condition of the legs was due to subcutaneous and intermuscular extravasations, especially in the calves, but also affecting the anterior tibial muscles. There was no skin eruption of any kind. Diarrhœa had never been present nor had any external hæmorrhages occurred. The alkalinity of the blood was found to be $\frac{N}{30}$, and the blood coagulation time was about four minutes. Since admission to the hospital the patient had been treated with lime-juice and citrate of iron and quinine along with a special diet. As all the five cases which I had under my observation in the jail at this time received this diet I shall mention it more in detail later. No improvement had taken place under this treatment. The further progress of this case was interesting. On the 27th the lime-juice and citrate of iron and quinine were stopped and lactate of soda (60 grains daily) was substituted. The special diet was continued. In spite of this treatment the patient got gradually worse and died on Oct. 11th. In my absence Dr. Moos made a necropsy. He reported that he found the usual intermuscular extravasations and serous effusions which are met with in fatal cases of scurvy.

CASE 2.—The patient was a Hindu of the Koli caste, aged 35 years, who had been imprisoned on Jan. 3rd, 1900. The patient was admitted into hospital on Sept. 5th presenting the usual symptoms of scurvy. He came under my direct observation on the 25th, when his condition was as follows: The gums were markedly swollen and spongy and bled readily. The teeth were very loose. There was a large unhealthy-looking ulcer over the right inner malleolus. There was considerable œdema of both feet and legs. The calves were swollen, hard, hot to the touch, and brawny in appearance. There were no subcutaneous ecchymoses. The alkalinity of the blood was found to be $\frac{N}{30}$ and the blood coagulation time was four and a quarter minutes. Since admission to hospital there had been neither diarrhœa nor external bleeding. He had been treated with lime-juice and citrate of iron and quinine, as well as receiving the extra diet to be mentioned hereafter. There had been no improvement in his condition under this treatment. On the 27th the lime-juice and citrate of iron and quinine were stopped. Instead of these medicines lactate of soda (60 grains daily) was administered, the special diet being at the same time continued. On Oct. 6th the fæces were examined for ova of dochmius duodenalis. The results of this examination were negative. On the 12th Dr. Moos reported that there had been no improvement since the new treatment was begun. After this date, however, the patient began to improve slightly and was ultimately discharged cured on Nov. 30th.

CASE 3.—The patient was a Hindu of the Koli caste, aged 28 years, who had been imprisoned on June 6th, 1900. He was admitted into hospital on Sept. 17th, 1900, presenting the usual symptoms of scurvy. He had only recently recovered from an attack of cholera. He came under my observation on the 25th, when his condition was as follows. The gums were spongy, although not so markedly spongy as in Case 1 and Case 2. The right leg below the knee was much swollen, hard, and painful, with marked œdema of the foot. The left leg was normal. The alkalinity of the blood was found to be $\frac{N}{35}$. Since admission to hospital there had been no diarrhœa or external hæmorrhage. He had been treated with citrate of iron and quinine as well as the extra diet, the same as in Case 1 and Case 2. He had had no lime-juice. There had been no improvement in his condition since admission. On the 27th the citrate of iron and quinine were stopped and lactate of soda (20 grain doses three times a day) was substituted. The extra diet was continued. On Oct. 6th the fæces were examined for ova of ankylostoma duodenale. The examination was negative. On the 12th Dr. Moos wrote to me that there had been no, or only very slight, improvement since the patient had been admitted to the hospital, but after this date he gradually improved and was discharged practically well on Nov. 12th.

CASE 4.—The patient was a Hindu of the Agree caste, aged 40 years, who had been imprisoned on Sept. 3rd, 1899. He was admitted into hospital on Sept. 18th, 1900, when he showed slight symptoms of scurvy. He came under my observation on the 25th, when his condition was as follows. There was only slight sponginess of the gums; the teeth were all very loose. There was well-marked œdema of the left foot, while the left leg below the knee was swollen, hard, and brawny. Great pain was complained of on the slightest pressure of this leg. The right leg and foot were normal. The alkalinity of the blood was found to be $\frac{N}{30}$. Since his admission to the hospital there had been neither diarrhœa nor any external hæmorrhage. Patient had been treated with citrate of iron and quinine as well as the special diet. No lime-juice had been given. On this treatment there had been very slight or no improvement. On the 27th the citrate of iron and quinine were stopped and the administration of lactate of soda (60 grains per diem) was begun. The extra diet was continued. On Oct 6th the fæces were examined carefully for ova of ankylostoma duodenale. The result of this examination was negative. On the 12th Dr. Moos reported that there had been no further improvement since the lactate of soda was begun. A month later (on Nov. 12th) the patient was discharged cured.

---

[6] THE LANCET, Sept. 18th, 1897, p. 719.

CASE 5.—The patient was a Hindu of the Lincayeb caste, aged 45 years, who had been imprisoned on Oct. 23rd, 1899. He was admitted into hospital on Sept. 5th, 1900, showing some of the usual symptoms of scurvy. He came under my observation on the 25th when his condition was as follows. There was only slight sponginess of the gums. Both legs below the knee were much swollen, hard, brawny, and extremely painful on the slightest pressure. There was well-marked œdema of both feet. The alkalinity of the blood was estimated to be $\frac{N}{30}$. Since admission to the hospital the patient's condition had remained *in statu quo*. During this time he had not suffered from diarrhœa nor had there been any external hæmorrhage. No lime-juice had been given. He had been treated with citrate of iron and quinine and was also given the special diet. On the 27th lactate of soda (60 grains daily) was substituted for the citrate of iron and quinine. The special diet was continued. On Oct. 6th an examination of the fæces was made for the ova of dochmius duodenalis No ova were found On the 12th Dr. Moos reported that there had been no improvement in the symptoms since the patient's admission to the hospital. On Nov. 14th the patient was discharged to light work.

Before proceeding to record the remaining six cases, who were natives from the bazaar under treatment in a general hospital in Bombay, it would be well to consider further the well-marked series of cases detailed above and to draw attention to a few points which bear on the questions under discussion.

In the first place, then, as regards the etiology of these cases it is interesting and important to be able to put on record the dietary which these patients had been fed upon before admission to hospital, for inasmuch as all these men had been resident in the jail for periods varying from three to twelve and a half months before symptoms of scurvy developed it is evident that any error or deficiency in diet before their incarceration can hardly be brought forward as a factor in the etiology of the scorbutic symptoms. The scale of this diet may be tabulated as follows:—

TABLE I.—*Showing the Scale of Ordinary Diet of Prisoners.*

| Articles. | Sunday. | Monday. | Tuesday. | Wednesday. | Thursday. | Friday. | Saturday. |
|---|---|---|---|---|---|---|---|
| | Oz. | Oz | Oz. | Oz. | Oz | Oz. | Oz |
| Wheat flour or rice | 12 | *Nil* | *Nil.* | 12 | *Nil* | *Nil.* | *Nil* |
| Jowari, bajiri, or nagli flour . ... .. ... | 12 | 24 | 24 | 12 | 24 | 24 | 24 |
| Dhall toor* ... . ... | *Nil* | 5 | 5 | 5 | 5 | 5 | 5 |
| Mutton (without bone) | 4 | *Nil* | *Nil.* | *Nil.* | *Nil.* | *Nil* | *Nil* |

| | Dr. | Dr | Dr | Dr. | Dr | Dr. | Dr |
| Onions .. . | 4 | 4 | 4 | 4 | 4 | 4 | 4 |
| Condiments .. .. . | 4 | 4 | 4 | 4 | 4 | 4 | 4 |
| Salt ... ... ... ... ... | 8 | 8 | 8 | 8 | 8 | 8 | 8 |
| Oil .. ... ... ... | Six drachms daily between April 1st and Sept. 30th; 10 drachms daily between Oct. 1st and March 31st. | | | | | | |
| Tamarinds (without husk and seeds) .. .. | Four drachms daily between April 1st and Sept. 30th; two drachms daily between Oct. 1st and March 31st. | | | | | | |

* A pulse similar to the lentil.
† Vegetables consist of potato, bringal, bhagee, and sweet gourds.

Considered in the light of Professor Wright's hypothesis it is manifest that the ordinary jail diet cannot be said to be deficient in fresh vegetables. No less than half a pound of these is given daily. It is therefore unlikely that the acid food-stuffs (viz., the cereals and meat) here preponderated over the alkaline food-stuffs (viz., the fresh vegetables, onions, and dhall) in such a manner as to bring about a condition of acid intoxication. Now the jail diet which has been tabulated above is practically the same diet which is in use by the great majority of the natives of India living in their natural conditions, and it cannot be said that scurvy is at all common among them. Further, when we consider that out of an average population of 1095 prisoners these five patients, along with one other who had just died before they came under my observation, were the only cases which had occurred in this jail for some time, and when we consider that all prisoners are fed on practically the same diet—the slight differences in the various scales of diet depending upon the work which each man has to perform—it would seem useless to look for a cause of this limited outbreak of scurvy to any *deficiency in dietary. Had such a general* cause as deficiency or error in diet been operative one would have expected a much greater number of cases to have taken place. Further, the diet is a fixed one and under control and careful inspection. It is, moreover, just sufficient for the work done and does not satisfy hunger so thoroughly as to lead one to think, notwithstanding the known artfulness of the Indian prisoner in malingering, that it is likely that a prisoner would willingly pass over any item in the bill of fare for the purpose of producing scorbutic symptoms. It is also doubtful as to whether or not he would have sufficient intelligence or scientific knowledge to enable him successfully to malinger in this way. We may therefore take it as almost certain that there is no waste and that the regulation diet is all consumed. These facts relating to the dietary therefore lend no support to Professor Wright's hypothesis that scurvy is always associated with a diet in which the alkaline food-stuffs are deficient.

Again, the ptomaine theory of the etiology of scurvy put forward by Mr. Jackson and Dr. Harley receives no support from a consideration of the diet-table detailed above, for a glance will show that the patients had only been receiving four ounces of fresh mutton once a week. Further, as in Indian jails meat is eaten the same day as that on which the animal is killed and is subjected to careful inspection, there can be no question as to the development of bacterial poison in the meat before consumption.

In harmony with the inferences based on the consideration of the dietary are the results of the blood examination. We have seen that no diminution in the alkalinity of the blood serum was found to be present in any one of the cases which are detailed above. These cases all presented well-marked scorbutic symptoms and one of them was so severe that death took place a short time after it came under observation. This result, then, would definitely point to the conclusion that these cases of scurvy were, at any rate, not cases of acid intoxication. In consonance with the conclusion are the effects of treatment. We have noted above that the course of the disease was not in any instance noticeably affected by the treatment. This treatment consisted in the earlier period in an extra special diet, supplemented in two of the cases with a fairly large quantity of lime-juice. This extra diet consisted of the ordinary hospital diet given to non-working prisoners and, in addition, an extra allowance of milk, sugar, fresh mutton, potato, and ghee. The quantities of the various articles of the total diet are tabulated as follows:—

TABLE II.—*Showing the Scale of Diet of Prisoners suffering from Scurvy.*

| Articles. | Quantity. | How often. |
|---|---|---|
| Rice and wheat (jowari, bajiri, or nagli) ... ... ... ... . .. . | 18 ounces. | Daily. |
| Dhall toor ... . ... ... .. ... | 5 ,, | ,, |
| Milk ... ... ... ... . . ... .. | 1 pound. | ,, |

| Condiments ... ... ... ... ... . | 4 drachms. | ,, |

No improvement of the condition had followed this treatment. On the first day on which I saw the patients I asked Dr. Moos to continue this diet, but to substitute lactate of soda for the lime-juice and any other medicine they were taking. This request was made before the result of the blood serum examination was known, but not a grain of this drug had been given before the blood had been collected. Professor Wright[7] has recorded that in the cases of scurvy which he observed (these were cases which were associated with a marked diminution in the alkalinity of the blood) marked and rapid improvement followed immediately on the administration of lactate of soda and other similar substances, some of the patients, in fact, being rescued from the jaws of death.

We have seen that in my cases, which, as I have shown, were not associated with any diminution in the alkalinity of the blood, lactate of soda, although given in large doses—viz., 60 grains daily—brought about no improvement whatever in the clinical aspect of the cases. One case, indeed, ended fatally 17 days after the exhibition of this drug was begun. The facts, therefore, which go to show that these cases, although presenting all the symptoms of the scorbutic condition, were not cases of acid intoxication due to a dietary deficient in alkaline food-stuffs, may be briefly summarised as follows.

1. There was no marked deficiency in the alkaline food-stuffs of the dietary before the onset of the symptoms. The diet was common to about 1095 prisoners, and of these only six men developed scorbutic symptoms.

2 There was no diminution of the alkalinity of the blood serum observed when the symptoms were well marked.

3. There was no improvement in the symptoms either as a result of the giving of a diet consisting of abundant alkaline food-stuffs or on the administration of large doses of lactate of soda.

The remaining six cases which I have to record bear out the same conclusions. These cases were all patients in the Jamsetjee Jeejeebhoy Hospital, Bombay. They had been admitted from the streets suffering from the symptoms detailed below. It was found impossible in any of these cases to get a reliable history of the quantity or of the exact nature of the diet on which the patients had been living before admission into the hospital. I am greatly indebted to the several physicians under whose care these cases were being treated for affording me every facility for examining them and for furnishing me with the clinical notes of the cases. The cases are given here in chronological order.

CASE 6.—This case was under the care of Major L. F. Childe, I.M.S., professor of pathology, Grant Medical College. The patient was a Hindu, aged 30 years. He was admitted into the hospital on Nov. 14th, 1900, and he came under my observation two days later. During this interval he had had no treatment of any kind. His condition on the 16th was as follows. The teeth were very loose; the gums were spongy and bleeding and were separated from the teeth. There was considerable œdema of the right foot. The right leg from the knee to the ankle was much swollen, hard, and very painful on pressure. There was no purpuric eruption; diarrhœa was present, the stools numbering three or four per diem; there had been no hæmorrhage from the bowel. The conjunctivæ were pale and indicated a certain amount of anæmia. The red blood cells numbered 4,000,000 per cubic millimetre. The blood coagulation time was four and three quarter minutes. The alkalinity of the blood was $\frac{N}{30}$. An examination of the fæces was made for ova. In all three slides were examined. The following ova were found: (1) one ovum of trichocephalus dispar; (2) one ovum of ascaris lumbricoides; and (3) one ovum of dochmius duodenalis. The treatment adopted by Major Childe was as follows. The usual diet of hospital patients of Hindu caste was given. This consisted principally of rice and vegetables. As well some alkaline mixtures consisting chiefly of sulphate of magnesium and citrate of potash were administered. The patient was discharged cured on Dec. 27th.

CASE 7.—This case was under the care of Dr. N. F. Surveyor. The patient was a Hindu woman, a widow, aged 24 years. She was admitted into the hospital on Oct. 29th, 1900, complaining of swelling of the left leg and pain in the right knee-joint. She was seen by me on Nov. 27th, when her condition was as follows. She was very thin, although not markedly anæmic. The red blood cells numbered 3,600,000 per cubic millimetre. The gums were spongy, but were neither ulcerated nor bleeding. Diarrhœa was present. The stools contained mucus and blood. The diarrhœa, however, became less after admission. On the front of the right tibia there was a small subperiosteal swelling which was very painful on pressure. The calf of the left leg was swollen, hard, and brawny; it was very tender on pressure. There was considerable œdema of this foot. The anterior tibial region was also swollen, hard, and tender, although this condition was not so marked in this region as it was in the calf. The blood coagulation time was about one and a quarter minutes. The alkalinity of the blood was $\frac{N}{30}$. On Nov. 28th, six slides of fæces were examined for ova, but with the exception of one ovum of trichocephalus dispar, none were found. The future history of this case as supplied to me by Dr. Surveyor was as follows. On Dec. 2nd the patient began to get very feeble. From the 3rd to the 8th the temperature showed a marked evening rise each day. Diarrhœa became very troublesome, the stools containing much blood and mucus. On the 8th symptoms pointing to a cerebral hæmorrhage made their appearance. The patient died on that day. Unfortunately a post-mortem examination was not obtained. During her residence in hospital treatment had been directed to controlling the diarrhœa and as usual the routine treatment for scurvy had been given. She had taken also at different periods citrate of potash and digitalis, quinine, iodide of potash, and chlorate of potash as a mouth wash.

CASE 8.—This case also was under the care of Dr. Surveyor. The patient was a Hindu woman, aged 25 years. She was admitted into the hospital on Nov. 19th, 1900. She came under my observation on the 27th, when her condition was as follows. The gums were markedly swollen and spongy, and much ulcerated, and they bled readily on being touched. After admission the bleeding from the gums was very marked. It was controlled, however, by the internal administration of chloride of calcium. The patient was very anæmic, the red blood cells numbering 2,200,000 per cubic millimetre. The right leg below the knee was markedly swollen; it was hard, brawny, hot, and very painful to the touch; there was considerable œdema of this foot. On the left leg there was some swelling around the tendo Achillis; this swelling was also tender; there was also slight swelling of the left knee On the posterior surface of the right ulna there was a painful subperiosteal swelling about two inches long. This had only appeared the night before. There had been no diarrhœa She had been having lime-juice since admission, but no alkalies. The blood coagulation time was two minutes and the alkalinity of the blood was $\frac{N}{25}$. Four slides of fæces were examined, but no ova of any description were found. On Dec. 11th the patient was found to have greatly improved Since the last note, after a diminution of the calcium chloride to 15 grains per diem, there had been severe bleeding from the gums. This was easily controlled by increasing the calcium chloride again. The gums and swelling of the leg were much better than they were a fortnight before With the exception of the calcium chloride there had been no medicinal treatment. The patient was discharged from hospital on the 26th. There was then slight swelling of the right leg and ankle-joint. The gums were almost normal

CASE 9.—This case also was under the care of Dr. Surveyor. It was quite a mild case. The patient was a Hindu woman, aged 25 years. She was admitted into hospital on Dec 9th, 1900. She said that she had been ill for two months before this date. She came under my observation on the 11th when she complained of pain in most of the joints, but no effusion into any joint was observable. The gums were spongy, swollen, and bled easily on pressure. There had been no spontaneous bleeding from the gums. There were no extravasations, either subcutaneous or intermuscular, in either leg There was no œdema or purpura. The bowels were constipated. The temperature was normal. With the exception, therefore, of the condition of the gums there were no symptoms of scurvy. The blood coagulation time was four minutes. The red blood cells numbered 5,100,000 per cubic millimetre. The alkalinity of the blood was found to be $\frac{N}{25}$.

CASE 10.—This case was under the care of Major R. W. S. Lyons, I.M.S., professor of medicine, Grant Medical small rectal speculum was, however, passed into the vagina, but, as it was rather less than half the length of an ordinary Fergusson's speculum, it only showed the lower two inches of the vaginal walls, which were thinly covered with the yellow discharge above mentioned. I advised the patient to have the cervix dilated sufficiently to allow the interior of the body of the uterus to be examined with the finger. She consented to have this done, but as she wished to return to the north of England for a fortnight it was not till March 1st that she entered Fitzroy House. The next day, with the usual antiseptic precautions, a specially prepared laminaria tent was inserted into the cervix. To do this, owing to the narrowness of the vagina, it was necessary to have the patient anæsthetised. Speaking from memory, I believe I have only once before found it necessary to have the patient anæsthetised for the insertion of tents, so that it will be seen that the narrowness of the vagina was such as to cause real difficulty in dealing with the case. On March 3rd the dilatation of the cervix was completed under an anæsthetic with Hegar's dilators. A growth was found high up in the endometrium. A portion of it was removed for microscopical examination, though I felt little doubt after the digital examination of the endometrium that the growth was malignant. The portion of growth removed was sent to the Clinical Research Association and Mr. J. H. Targett reported that it was carcinomatous. The patient was accordingly advised to have the uterus removed, and to this she consented.

---

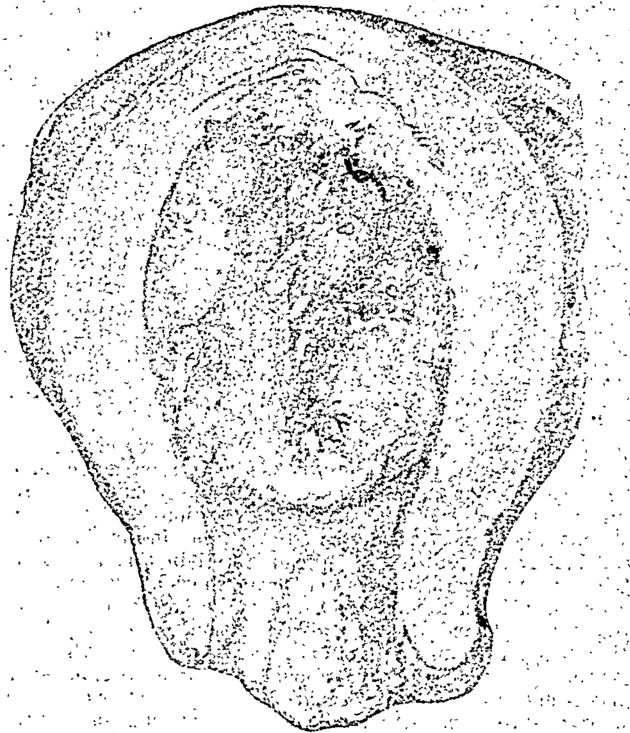
[7] THE LANCET, August 25th, 1900, p. 565.

The operation was performed on April 11th. The preliminary dilatation of the cervix for diagnosis had been so difficult on account of the narrowness of the vagina that I decided to remove the uterus by abdominal pan-hysterectomy. The method was the same as that adopted in four cases of pan-hysterectomy for fibroids, an account of which has already been published.[1] In this case the vagina was douched with a solution of perchloride of mercury (1 in 1000) just before the operation, but I did not make any attempt to occlude the cervix by a suture, or to pack it before beginning the abdominal section. The right uterine appendages were removed with the uterus, but the left appendages were not removed. The ligatures on the uterine arteries and on vessels in the cut edges of the vaginal walls were left long and drawn down into the vagina by long Wells's forceps passed up from the vagina by an assistant. A gauze drain was drawn down from above into the vagina, about an inch of it being left projecting into the peritoneum. The abdominal wound was completely closed. The patient made an uninterrupted recovery, and the ligatures came away at the end of the fifth week.

The following is a description of the specimen: "The uterus has been laid open by an incision from the external os to the fundus through the anterior wall. The extreme length of the uterus is three inches. At the extreme highest point of the endometrium, and extending downwards for an inch and a quarter on the posterior wall, is a new growth projecting only slightly above the general surface of the endometrium. Its surface is faintly papillary. A sagittal section has also been made through the growth and the wall of the uterus from which it springs. This shows that the growth penetrates deeply into the uterine wall, the limit of its penetration, to the naked eye, being marked by a sinuous, irregular, whitish border." A portion of the growth was sent to the Clinical Research Association and Mr. Targett reported on it as follows: "The wall of the uterus is deeply invaded by a very soft columnar-celled carcinoma. The growth is much degenerated and therefore stains badly. It is a primary carcinoma of the body of the uterus."

CASE 2.—A woman, aged 57 years, was admitted under my care into the London Hospital on Oct. 5th, 1901, at the request of Dr. W. C. Taylor of Victoria Dock-road, London, E. She had been married for 36 years, and had had six children, the last 21 years ago, and two miscarriages, the last 19 years ago. Menstruation began when she was between 16 and 17 years of age and occurred regularly every four weeks without any pain. Two and a half years ago menstruation ceased for 10 months. Then the periods came on for three months at monthly intervals. Each of these periods was like what she had always had except that she lost a larger quantity than formerly and clots were passed. She had been subject to bronchitis and asthma up to last year; she used to have quinsy 20 years ago. There was no history of syphilis, nor had she ever had any severe illness. Her family history was good. Two and a half years ago the periods ceased for 10 months, then they recurred three times at monthly intervals; after that, however, the loss of blood became more or less continuous. Sometimes clots were passed, but the discharge was never offensive. The discharge during the previous three months had not been quite so profuse as before, but she had had constantly to wear a diaper. Since April she had had pain on the right side running from the back to the right groin, and also aching in the right thigh. It was not constant, for sometimes she would be free from pain for 12 hours. When present it was aching, with an occasional severe shooting or cramping feeling. Sometimes the pain made her sick, and caused her to perspire, especially at night. It was relieved by sitting up or by walking about, and sometimes by alcohol. She had had no trouble with micturition, but the bowels had been constipated and she took aperients frequently. During the eight months before admission she had lost two stones in weight. From the above account it appears that there had been more or less constant blood-stained discharge for about 17 months and that she had had pain for six months prior to her admission to the hospital. On admission she was found not to be anæmic. She had a rather worried expression. Her weight was nine stones two pounds. On the 7th she was anæsthetised and a careful examination was made with the patient in the lithotomy position. With Sims's speculum it was seen that the vaginal portion of the cervix was healthy except for a slight erosion on the posterior lip. The cervix when drawn upon with a volsella did not come down well. Bimanually the uterus was found to be enlarged, but only fairly moveable; the sound passed three and a half inches. The cervix was dilated up to Hegar's dilator No. 19 without any difficulty, there being only slight resistance as each dilator was passed, and that at the external os. The finger passed into the uterus came upon a growth, chiefly on the posterior wall; it was not of the soft papillary variety. It terminated below by a raised, somewhat rounded border. The growth extended so low in the body of the uterus that it was not quite certain at this examination that the growth had not extended into the cervical canal. (Subsequent examination of the specimen, however, showed that it had not involved

FIG. 2.



The uterus removed in Case 2 and laid open by an incision through the anterior wall. *The malignant growth occupies nearly all the endometrium and terminates below by a raised border slightly convex towards the internal os.* It is worth noticing that, contrary to the usual experience in similar cases, the patient from whom this specimen was removed had been pregnant 8 times. (The specimen was shown at the meeting of the Obstetrical Society of London on Jan. 1st.)

---

[1] THE LANCET, July 8th, 1899, p. 82.

the cervix.) There was no offensive smell about the examining finger.

The operation was performed on the 14th. The patient was anæsthetised and put in the lithotomy position. After disinfecting the vagina as well as possible with a lotion of perchloride of mercury (1 in 1000) the cervix was exposed and seized with a volsella. A stout silk ligature was passed through the vaginal portion with a strong needle in a handle from behind forwards on the left side of the os uteri. The needle, unthreaded, was then passed similarly on the right side of the os, threaded with the anterior end of the ligature already passed, and withdrawn. The ligature was then tied as tightly as possible, thus occluding the external os. The patient was then put into the Trendelenburg position and abdominal pan hysterectomy was performed. The right uterine appendages were removed, but the left appendages were allowed to remain. There were some adhesions on the left side which had to be separated before the uterus could be drawn out freely. The limited mobility of the uterus observed at the previous examination was no doubt due to these adhesions. When the uterus had been removed all the ligatures were drawn into the vagina and a strip of iodoform gauze was also drawn into the vagina. About one inch of it was left projecting into the peritoneal cavity. The abdominal wound was then completely closed. The subsequent progress of the case was uneventful. The ligatures were not loose when she left the hospital, they were cut a good deal shorter a few days before she went away so that it would be impossible for any of them to project from the vagina. She went to a convalescent home on Nov. 9th.

The following is a description of the specimen: "The uterus has been laid open from the front. Its extreme length is three and three quarter inches. The cervix to the naked eye appears quite healthy, and is very short. Almost the whole of the endometrium is occupied by a new growth; this is raised about a quarter of an inch above the general level and its edge distinctly overhangs the adjacent apparently healthy endometrium. In the downward direction the growth extends very nearly to the internal os and terminates by a semicircular border convex downwards." A portion of the growth was sent to the Clinical Research Association and Mr. Targett reported on it as follows: "This is a columnar celled carcinoma of the body of the uterus originating in the endometrium and invading the muscular coat. The tubular arrangement of the cells is very distinct."

Harley-street, W.

# ON TWO CONTRASTED CASES OF HYSTERECTOMY: ONE DURING PREGNANCY, THE OTHER IN PUERPERY.

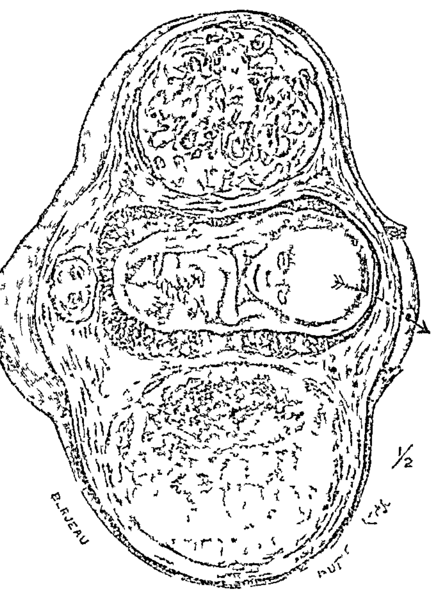
BY J. BLAND SUTTON, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

ON August 28th, 1901, at the Middlesex Hospital I performed abdominal hysterectomy on two patients for conditions in regard to the proper treatment of which gynæcologists and obstetricians hold anything but unanimous opinions. The two cases stand in striking contrast for in Case 1 the operation was undertaken with the view of averting a dangerous condition which had actually supervened in Case 2 and not only placed the patient's life in the gravest peril but surrounded the operation and the convalescence with great danger.

CASE 1.—A well developed woman, 28 years of age, sought advice for an abdominal swelling which she said, had recently grown much larger and had become painful. On careful inquiry we elicited two very important facts—first, that her menstruation never profuse, had been in abeyance three months. On examination a hard rounded swelling as big as a fist occupied the right iliac fossa; a larger rounded tumour could be felt immoveably impacted in the pelvis to the left of the cervix, whilst the vaginal portion of the cervix was pushed to the left side and in order to reach it the finger had to sweep over the rounded contour of the impacted tumour which appeared to usurp all the available space in the true pelvis. Pressure on the tumour caused pain and there was some difficulty with the rectum, but fortunately there was no interference with the bladder. The nature of the case was very clear—namely, fibroids impacted by pregnancy. So firmly was the tumour incarcerated that I had no hesitation in recommending the patient to submit to operation. I was very careful to explain to the class the reason for this advice. When the uterus is distorted by fibroids and so much displaced as in this case abortion is sure to occur, the damage to the fibroid which is inevitable in such circumstances would place the patient's life in the gravest peril if she should become septic. Even apart from this risk we now realise that pregnancy in itself leads to some little understood changes in fibroids quite apart from septic infection. In deciding the question of pregnancy I was careful to point out that there were no physical facts to guide me but I relied on the three months' amenorrhœa in a buxom woman, her statement that the tumour had lately very markedly increased in size, and the firmness of the impaction.

At the operation the uterus was found to be more displaced than had been anticipated. A large tumour in the anterior wall was impacted in the pelvis, the gravid uterine body was situated in the hypogastrium and the tumour in the posterior wall of the uterus occupied the right iliac fossa, so that the uterus was not only rotated through 90°, but also acutely flexed. I performed supra-vaginal hysterectomy and left both ovaries and Fallopian tubes, as they appeared healthy. The patient made a quick and satisfactory convalescence.

The uterus with the tumours was carefully hardened and then sectioned in a sagittal direction (see Figure). It measured in its antero-posterior (sagittal) axis 20 centimetres after it had been hardened and as the conjugate diameter of the pelvis is at most 10 centimetres it is clear that a great amount of rotation had slowly taken place to allow the parts to accommodate themselves in the pelvis. I have already drawn attention in THE LANCET[1] to a very similar case. The tumours in this specimen on section exhibited irregular dark red streaks; they were most marked in the larger tumour which had in addition undergone myxomatous changes and its central portion was diffluent.



A gravid uterus shown in section. It is deformed by fibroids. Removed from a woman 23 years of age. The arrow lies in the cervical canal.

CASE 2.—This patient was a married woman, 36 years of age. In 1896 she had been delivered of a healthy child. Two years later a fibroid of the size of a turkey's egg was small rectal speculum was, however, passed into the vagina, but, as it was rather less than half the length of an ordinary Fergusson's speculum, it only showed the lower two inches of the vaginal walls, which were thinly covered with the yellow discharge above mentioned. I advised the patient to have the cervix dilated sufficiently to allow the interior of the body of the uterus to be examined with the finger. She consented to have this done, but as she wished to return to the north of England for a fortnight it was not till March 1st that she entered Fitzroy House. The next day, with the usual antiseptic precautions, a specially prepared laminaria tent was inserted into the cervix. To do this, owing to the narrowness of the vagina, it was necessary to have the patient anæsthetised. Speaking from memory, I believe I have only once before found it necessary to have the patient anæsthetised for the insertion of tents, so that it will be seen that the narrowness of the vagina was such as to cause real difficulty in dealing with the case. On March 3rd the dilatation of the cervix was completed under an anæsthetic with Hegar's dilators. A growth was found high up in the endometrium. A portion of it was removed for microscopical examination, though I felt little doubt after the digital examination of the endometrium that the growth was malignant. The portion of growth removed was sent to the Clinical Research Association and Mr. J. H. Targett reported that it was carcinomatous. The patient was accordingly advised to have the uterus removed, and to this she consented.

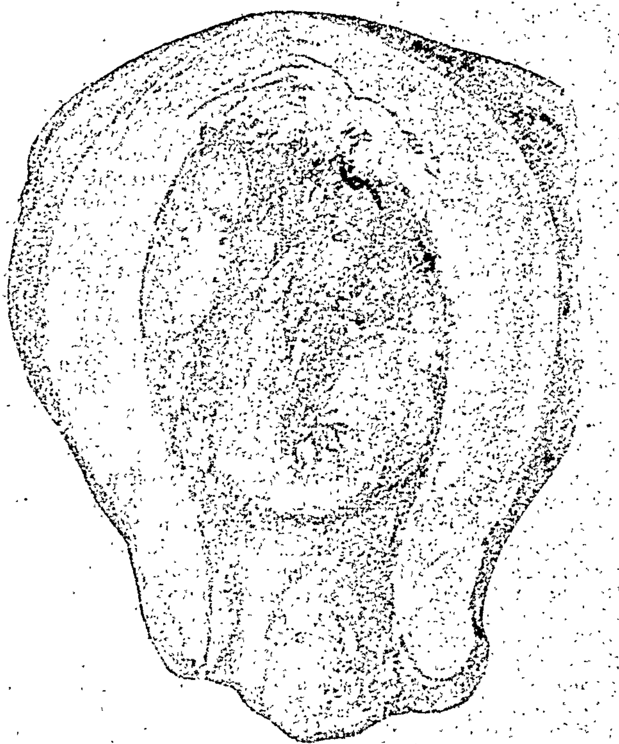
---

[1] THE LANCET, Feb. 16th, 1901, p. [illegible]

The operation was performed on April 11th. The preliminary dilatation of the cervix for diagnosis had been so difficult on account of the narrowness of the vagina that I decided to remove the uterus by abdominal pan-hysterectomy. The method was the same as that adopted in four cases of pan-hysterectomy for fibroids, an account of which has already been published.[1] In this case the vagina was douched with a solution of perchloride of mercury (1 in 1000) just before the operation, but I did not make any attempt to occlude the cervix by a suture, or to pack it before beginning the abdominal section. The right uterine appendages were removed with the uterus, but the left appendages were not removed. The ligatures on the uterine arteries and on vessels in the cut edges of the vaginal walls were left long and drawn down into the vagina by long Wells's forceps passed up from the vagina by an assistant. A gauze drain was drawn down from above into the vagina, about an inch of it being left projecting into the peritoneum. The abdominal wound was completely closed. The patient made an uninterrupted recovery, and the ligatures came away at the end of the fifth week.

The following is a description of the specimen: "The uterus has been laid open by an incision from the external os to the fundus through the anterior wall. The extreme length of the uterus is three inches. At the extreme highest point of the endometrium, and extending downwards for an inch and a quarter on the posterior wall, is a new growth projecting only slightly above the general surface of the endometrium. Its surface is faintly papillary. A sagittal section has also been made through the growth and the wall of the uterus from which it springs. This shows that the growth penetrates deeply into the uterine wall, the limit of its penetration, to the naked eye, being marked by a sinuous, irregular, whitish border." A portion of the growth was sent to the Clinical Research Association and Mr. Targett reported on it as follows: "The wall of the uterus is deeply invaded by a very soft columnar-celled carcinoma. The growth is much degenerated and therefore stains badly. It is a primary carcinoma of the body of the uterus."

FIG. 2.



The uterus removed in Case 2 and laid open by an incision through the anterior wall. The malignant growth occupies nearly all the endometrium and terminates below by a raised border slightly convex towards the internal os. It is worth noticing that, contrary to the usual experience in similar cases, the patient from whom this specimen was removed had been pregnant 8 times. (The specimen was shown at the meeting of the Obstetrical Society of London on Jan. 1st.)

CASE 2.—A woman, aged 57 years, was admitted under my care into the London Hospital on Oct. 5th, 1901, at the request of Dr. W. C. Taylor of Victoria Dock-road, London, E. She had been married for 36 years, and had had six children, the last 21 years ago, and two miscarriages, the last 19 years ago. Menstruation began when she was between 16 and 17 years of age and occurred regularly every four weeks without any pain. Two and a half years ago menstruation ceased for 10 months. Then the periods came on for three months at monthly intervals. Each of these periods was like what she had always had except that she lost a larger quantity than formerly and clots were passed. She had been subject to bronchitis and asthma up to last year; she used to have quinsy 20 years ago. There was no history of syphilis, nor had she ever had any severe illness. Her family history was good. Two and a half years ago the periods ceased for 10 months, then they recurred three times at monthly intervals; after that, however, the loss of blood became more or less continuous. Sometimes clots were passed, but the discharge was never offensive. The discharge during the previous three months had not been quite so profuse as before, but she had had constantly to wear a diaper. Since April she had had pain on the right side running from the back to the right groin, and also aching in the right thigh. It was not constant, for sometimes she would be free from pain for 12 hours. When present it was aching, with an occasional severe shooting or cramping feeling. Sometimes the pain made her sick, and caused her to perspire, especially at night. It was relieved by sitting up or by walking about, and sometimes by alcohol. She had had no trouble with micturition, but the bowels had been constipated and she took aperients frequently. During the eight months before admission she had lost two stones in weight. From the above account it appears that there had been more or less constant blood-stained discharge for about 17 months and that she had had pain for six months prior to her admission to the hospital. On admission she was found not to be anæmic. She had a rather worried expression. Her weight was nine stones two pounds. On the 7th she was anæsthetised and a careful examination was made with the patient in the lithotomy position. With Sims's speculum it was seen that the vaginal portion of the cervix was healthy except for a slight erosion on the posterior lip. The cervix when drawn upon with a volsella did not come down well. Bimanually the uterus was found to be enlarged, but only fairly moveable; the sound passed three and a half inches. The cervix was dilated up to Hegar's dilator No. 19 without any difficulty, there being only slight resistance as each dilator was passed, and that at the external os. The finger passed into the uterus came upon a growth, chiefly on the posterior wall; it was not of the soft papillary variety. It terminated below by a raised, somewhat rounded border. The growth extended so low in the body of the uterus that it was not quite certain at this examination that the growth had not extended into the cervical canal. (Subsequent examination of the specimen, however, showed that it had not involved the cervix ) There was no offensive smell about the examining finger

---

[1] THE LANCET, July 8th, 1899, p. 82.

The operation was performed on the 14th The patient was anæsthetised and put in the lithotomy position After disinfecting the vagina as well as possible with a lotion of perchloride of mercury (1 in 1000) the cervix was exposed and seized with a volsella A stout silk ligature was passed through the vaginal portion with a strong needle in a handle from behind forwards on the left side of the os uteri. The needle unthreaded was then passed similarly on the right side of the os threaded with the anterior end of the ligature already passed and withdrawn The ligature was then tied as tightly as possible, thus occluding the external os The patient was then put into the Trendelenburg position and abdominal pan hysterectomy was performed The right uterine appendages were removed, but the left appendages were allowed to remain There were some adhesions on the left side which had to be separated before the uterus could be drawn out freely The limited mobility of the uterus observed at the previous examination was no doubt due to these adhesions When the uterus had been removed all the ligatures were drawn into the vagina and a strip of iodoform gauze was also drawn into the vagina About one inch of it was left projecting into the peritoneal cavity The abdominal wound was then completely closed The subsequent progress of the case was uneventful The ligatures were not loose when she left the hospital , they were cut a good deal shorter a few days before she went away, so that it would be impossible for any of them to project from the vagina She went to a convalescent home on Nov 9th

The following is a description of the specimen The uterus has been laid open from the front Its extreme length is three and three quarter inches The cervix to the naked eye appears quite healthy and is very short Almost the whole of the endometrium is occupied by a new growth , this is raised about a quarter of an inch above the general level and its edge distinctly overhangs the adjacent apparently healthy endometrium In the downward direction the growth extends very nearly to the internal os and terminates by a semicircular border convex downwards A portion of the growth was sent to the Clinical Research Association and Mr Targett reported on it as follows "This is a columnar celled carcinoma of the body of the uterus originating in the endometrium and invading the muscular coat The tubular arrangement of the cells is very distinct

# ON TWO CONTRASTED CASES OF HYSTERECTOMY ONE DURING PREGNANCY, THE OTHER IN PUERPERY

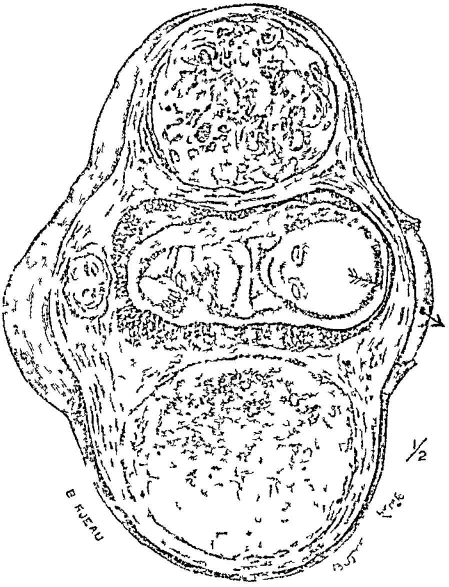
BY J BLAND SUTTON, F R C S ENG ,
ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL

ON August 28th, 1901 at the Middlesex Hospital I performed abdominal hysterectomy on two patients for conditions in regard to the proper treatment of which gynæcologists and obstetricians hold anything but unanimous opinions The two cases stand in striking contrast for in Case 1 the operation was undertaken with the view of averting a dangerous condition which had actually supervened in Case 2 and not only placed the patient s life in the gravest peril but surrounded the operation and the convalescence with great danger

CASE 1 —A well developed woman 28 years of age sought advice for an abdominal swelling which she said had recently grown much larger and had become painful On careful inquiry we elicited two very important facts—first that her menstruation never profuse had been in abeyance three months On examination a hard rounded swelling as big as a fist occupied the right iliac fossa a larger rounded tumour could be felt immoveably impacted in the pelvis to the left of the cervix, whilst the vaginal portion of the cervix was pushed to the left side and in order to reach it the finger had to sweep over the rounded contour of the impacted tumour which appeared to usurp all the available space in the true pelvis Pressure on the tumour caused pain and there was some difficulty with the rectum but fortunately there was no interference with the bladder The nature of the case was very clear—namely, fibroids impacted by pregnancy So firmly was the tumour incarcerated that I had no hesitation in recommending the patient to submit to operation. I was very careful to explain to the class the reason for this advice When the uterus is distorted by fibroids and so much displaced as in this case abortion is sure to occur , the damage to the fibroid which is inevitable in such circumstances would place the patient s life in the gravest peril if she should become septic Even apart from this risk we now realise that pregnancy in itself leads to some little understood changes in fibroids quite apart from septic infection In deciding the question of pregnancy I was careful to point out that there were no physical facts to guide me, but I relied on the three months amenorrhœa in a buxom woman her statement that the tumour had lately very markedly increased in size and the firmness of the impaction

At the operation the uterus was found to be more displaced than had been anticipated A large tumour in the anterior wall was impacted in the pelvis, the gravid uterine body was situated in the hypogastrium and the tumour in the posterior wall of the uterus occupied the right iliac fossa so that the uterus was not only rotated through 90°, but also acutely flexed I performed supra vaginal hysterectomy and left both ovaries and Fallopian tube as they appeared healthy The patient made a quick and satisfactory convalescence

The uterus with the tumours was carefully hardened and then sectioned in a sagittal direction (see Figure) It measured in its antero posterior (sagittal) axis 20 centimetres after it had been hardened and as the conjugate diameter of the pelvis is at most 10 centimetre it is clear that a great amount of rotation had slowly taken place to allow the parts to accommodate themselves in the pelvis I have already drawn attention in THE LANCET[1] to a very similar case The tumours in this specimen on section exhibited irregular dark red streaks they were most marked in the larger tumour which had in addition undergone myxomatous changes and its central portion was diffluent.



A gravid uterus shown in section it is deformed by fibroids Removed from a woman 28 years of age The arrow lies in the cervical [illegible]

CASE 2 —This patient was a married woman 35 years of age In 1896 she had been delivered of a healthy child Two years later a fibroid of the size of a turkey s egg was detected in her hypogastrium. Towards the end of 1900 she became pregnant a second time and was delivered of the child in July, 1901. A few days after the birth of the child the fibroid became very tender and the woman had irregular losses of blood from the uterus. and at the end of three weeks she had a severe "flooding" which Mr. W. K. Loveless feared would end her life, and a repetition of this severe bleeding a few days later induced him to place the patient under my care. The woman was profoundly anæmic and had a tumour of the size of a cricket-ball, very tender, freely moveable, but sessile, in a puerperal uterus. A few days later I exposed the parts through an abdominal incision and found a smooth fibroid sessile on the anterior wall of the uterus, resembling in shape an acorn in its cup. The ovarian and uterine vessels were secured and the uterus with the tumour cut away at the junction of the body with its neck. Immediately a lot of fœtid fluid and débris escaped, but I had carefully isolated the parts with sterilised dabs. The ovaries and Fallopian tubes were then removed as the tubes contained pus. I did not dare to allow the stump to return into the pelvis, so after surrounding it with the parietal peritoneum and completely isolating it I imbedded it in the lower angle of the incision and secured it with sutures of fish-gut. For 10 days after the operation there was a free discharge of sloughs from the stump and also from the vagina, but by assiduous dressing the parts were kept sweet and they quickly cleaned. Five weeks after the operation the patient left the hospital convalescent.

---

[1] THE LANCET [illegible] 16th 1901, [illegible]

The tumour on section was of the colour of mahogany; its central parts and that segment of its circumference in relation with the uterine cavity were soft and almost diffluent. Bacteriologic examination of the solid peripheric portion of the tumour was negative and on microscopic investigation the tumour presented the structure of a typical fibro-myoma thickly splashed with blood pigment, but no obvious extravasation of blood corpuscles.

A careful study of a number of fibroids obtained from gravid uteri shows that under these conditions fibroids are very prone to undergo degenerative changes and are especially liable to soften. The peculiar alteration in colour is another feature which in my observations has been entirely confined to fibroids complicating pregnancy. The common colour of a fibroid is dirty-white or a very pale yellow; in many degenerating fibroids the yellow deepens In pregnancy the fibroid usually assumes a deep red or a mahogany tint. In the early stages the tumour exhibits this colour in streaks, but as the pregnancy advances the whole tumour becomes affected. The clinical facts of the two cases considered in this communication are interesting from another point of view. In ordinary circumstances fibroids are painless tumours, hence it may be taken as an axiom that *when a fibroid becomes painful it signifies that the tumour is undergoing secondary changes or that some complication has arisen in the pelvis.*

# THE DISAPPEARANCE OF THE ADDIMENT FROM ANTI-MICROBICS ERA.

By E. W. AINLEY WALKER, M.A., M.D. OXON.,
RADCLIFFE TRAVELLING FELLOW IN THE UNIVERSITY OF OXFORD; GORDON LECTURER IN EXPERIMENTAL PATHOLOGY, GUY'S HOSPITAL.

## A PRELIMINARY NOTE.

IN a previous communication[1] I have shown by animal experiments that the bacteriolytic addiment of fresh normal serum tends to disappear with considerable rapidity, and is no longer present in a serum which has been kept for several days. In order to examine further the phenomenon of its disappearance I have lately made experiments of which the following is a brief summary.

A number of rabbits were immunised by the successive injection of increasing doses of living typhoid culture and were subsequently bled for the preparation of serum. The sera thus obtained were examined for bacteriolytic action on the bacillus typhosus and were compared with the fresh sera of five normal healthy rabbits. The following procedure was employed. The blood was received in sterile test tubes, and so soon as fluid began to separate from the clot a specimen was removed. After an interval of from four to six hours from the time of bleeding a second specimen was taken, and at the end of 24 hours the remaining serum was separated from the clot and tubed for future use.

Anti-bacterial action was tested as follows. A given number of drops of the specimen of serum to be examined were measured into test tubes by means of a pipette, the same pipette being used throughout the observations. Each tube was then inoculated with one loopful of a typhoid culture grown for 24 hours in 10 cubic centimetres of bouillon. The tubes were incubated during a period of three hours; to each was then added a given quantity of gelatin which had been previously melted and the contents were thoroughly mixed and rapidly plated. Colonies were counted after three days' growth. In every case a control-plate was made with uninoculated serum to test its sterility, and another with one loopful of the typhoid culture inoculated for three hours in a few drops of ordinary bouillon for comparison with the inoculated serum. Where the colonies were numerous they were approximately estimated by means of an apparatus in which about 500 squares were equal to the area of the plates employed. Up to 100 colonies per square could be counted with the magnifying-glass with moderate accuracy. Above this number I have used the term "uncountable" where the colonies were obviously less numerous than those in the control without serum, and the sign ∞ where no such difference was appreciable. Where there were upwards of 5000 colonies the number is given approximately to the nearest 1000 and where the colonies were present in many thousands their number was estimated to the nearest 5000 or 10,000. The results are given in Table II., where N. 1, 2, 3, 4, 5 are sera of five healthy normal rabbits, and I., *a*, *b*, *c*, *d*, *e*, those of five rabbits lightly immunised against the bacillus typhosus under the following table (Table I.).

Similar observations made with the fresh sera of two horses immunised for the production of anti-streptococcic serum gave with a streptococcus virulent for animals the following results, the horse sera being denominated S. 1 and S. 2 :—

TABLE III.—*Streptococcus Plates.*

| Age of serum. | Drops of serum. | Strepto-coccus bouillon culture. | N. 4. | S. 1. | S. 2. |
|---|---|---|---|---|---|
| 1 hour ... | 5 | 1 loopful. | ∞ | — | 50,000 |
| | 10 | ,, | ∞ | — | 16,000 |
| 3 hours .. | 5 | ,, | ∞ | 1600 | — |
| | 10 | ,, | ∞ | 900 | — |
| 4 ,, ... | 5 | ,, | ∞ | — | 10,000 |
| | 10 | ,, | ∞ | — | 6,000 |
| 6 ,, ... | 5 | ,, | ∞ | 40,000 | — |
| | 10 | ,, | ∞ | 16,000 | — |
| 24 ,, ... | 5 | ,, | ∞ | Unc. | Unc. |
| | 10 | ,, | ∞ | 50,000 | 40,000 |
| 2 days ... | 5 | ,, | ∞ | ∞ | ∞ |
| | 10 | ,, | ∞ | Unc. | Unc. |
| 3 ,, ... | 5 | ,, | ∞ | ∞ | ∞ |
| | 10 | ,, | ∞ | ∞ | ∞ |

Unc. = uncountable. A dash signifies that no observation was made.

Several interesting points appear in these results with which I hope to deal more fully on a subsequent occasion, but that to which I wish at present more particularly to direct attention is the fact that the bacteriolytic power of a fresh serum rapidly diminishes both in the immune and in normal sera, and ceases to be recognisable within a few days from the time of bleeding. Hence it appears that as regards experiments in *bacteriolysis* the age of the serum which supplies the addiment is a factor of the first importance, and that observations on *bacteriolytic* action with an addiment-containing serum cannot be properly compared unless they are performed at the same time, since the *bacteriolytic*

# BEEF-WORM IN THE ORBITAL CAVITY

BY THOMAS W F GANN, M R C S ENG,
L R C P LOND, L S A,
DISTRICT SURGEON COROZAL BRITISH HONDURAS

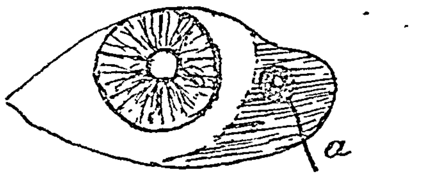
To anyone who has lived for any length of time in either Central America or South America the parasite known as the "beef worm" must be familiar either from hearsay or possibly from painful personal experience as, though fortunately not of common occurrence, it is one of the most distressing and painful of the innumerable insect pests of these regions

The creature starts in life as an egg which being laid by the parent fly beneath the human skin or mucous membrane soon hatches out into a small worm which rapidly increases in size and reaches in a few months a length of from one to two inches and a diameter of from three eighths to three-quarters of an inch The worm is of a dull greyish white colour, divided into from 12 to 20 segments and covered by stiff black hairs or bristles according to its age along the middle two thirds of its body each segment possessing a separate row of hairs completely surrounding its anterior and posterior margins The tail end communicates with the exterior by a circular orifice surrounded by a prominent raised margin, the head end being deeply embedded in the tissues and supplied with two strong semicircular, black hooks, by means of which it attaches itself firmly, rendering its expulsion extremely difficult. It advances and withdraws its tail with a sort of rhythmic motion which gives rise to the characteristic sensation of "something moving and alive" within the swelling caused by it upon the skin or mucous membrane. The parts most affected by this parasite are the extensor surfaces of the arms and legs, the back, and shoulders and the chest; but exceptional cases have been recorded of its occurrence in the face and even upon the penis.

Certain individuals appear to be particularly susceptible to the worm, and if one of these should go into a district infested by it he is practically certain to become the host of one or more. Negroes are far more susceptible than are whites. Other persons, again, appear to enjoy complete immunity from the pests; they may go into a district swarming with the worms, sleep on the ground out of doors without a net for months at a time and never get a single one, though other persons of the same colour and nationality would under similar circumstances be literally eaten alive. The worm appears to be limited to small and clearly-defined districts within which a man may, if he sleeps uncovered for a single night, be almost certain of contracting it, though less than a mile distant perfect immunity is enjoyed.

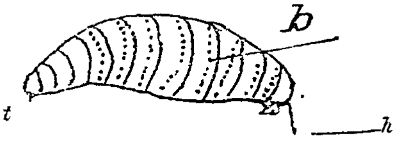
The present case of a beef-worm in the orbit is, so far as I am aware, unique. The patient, a Spanish lad, about 18 years of age, came to me on Sept. 16th, 1901, stating that he had been living for some considerable time in the bush and that during the last three months he had been suffering from pain and inconvenience in the left eye, together with a sensation as if something were moving about within the socket. On examination the eye was seen to be a good deal more prominent than its fellow; the conjunctiva was more or less congested throughout its whole extent and the entire inner canthus of the eye was enormously bulged forward. Immediately to the inner side of the caruncula lacrymalis was a circular opening about one-twelfth of an inch in diameter, surrounded by a prominent rim, and at the bottom of this opening appeared a small, whitish knob which from time to time was slightly protruded beyond the opening, but if touched it was immediately withdrawn so far back as to become almost invisible (Fig. 1). The negro method of treating the worm is first to cover the hole over with a plug of wet tobacco for a day or two, and then with great force to squeeze it out, the tobacco appearing to make the creature lose its hold with the hooks attached to its head. This method was obviously impossible in the eye, so I injected a few minims of a strong solution of tobacco into the aperture with a hypodermic syringe and then covered it over with a plug of moist tobacco-leaf and left it for a couple of hours. On removing the tobacco-plug I found the creature much less active, and after some little trouble I managed to seize the tail-end with a fine forceps and little by little to withdraw the whole worm. The patient made a good recovery and did not lose the sight of his eye.

FIG. 1.



Rough diagram of the eye of the patient, the shaded portion indicating the inflammation and protrusion of the inner canthus. *a*, Circular aperture with prominent raised margin through which the tail-end of the worm protruded from time to time.

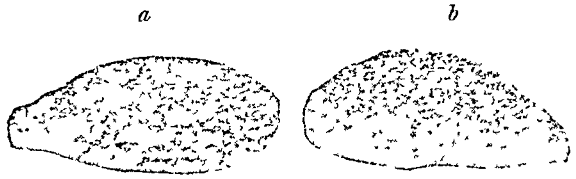
FIG. 2.



Rough diagram of the beef-worm. *h*, Head, showing two short black hooks with which the worm affixes itself to deep tissues; *t*, tail; and *b*, bristles. These bristles are set in rows around each segment of the middle two-thirds of the worm.

I inclose a rough sketch and two photographs of the worm (Figs. 2 and 3), as well as the creature itself preserved in alcohol; it measured when first extracted one and three-eighths inches in length by three-eighths of an inch in diameter and was covered over the middle two-thirds of its body by short dark bristles. It is only about half-grown, as in the full-grown worm these bristles attain a length of half an inch or more.

FIG. 3.



(*a*) The ventral aspect, and (*b*) the left dorsal aspect—of the actual worm; life-size. From photographs.

The curious point about this case is how the fly managed to lay its egg in such an exceedingly sensitive spot as the inner canthus of the eye without the sufferer becoming aware of the fact.

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### A CASE OF VAGINAL ATRESIA.

BY F. SIDNEY GRAMSHAW, M.D. ST. AND.

A WELL-DEVELOPED, tall girl, aged 18 years, was brought to me on Dec. 17th, 1901, under the suspicion that she was pregnant. She complained of much pain, and her abdomen was very hard and enlarged, so as to give the impression that she was at least seven months advanced in pregnancy. I ordered her to bed and found on examination that the breasts were quite virginal and that the abdomen was distended by what appeared to be a tumour of extreme hardness. The mother informed me that the girl had never menstruated. The vagina was perfectly occluded by a firm tense hymen which on examination presented no trace of any orifice or cicatrix. It bulged outwards, putting all the soft structures on the stretch. Having placed the patient in the lithotomy position I made a small transverse incision with a tenotomy knife, when a column of dark brown, thick grumous fluid spurted up more than two feet into the air. I inserted a tube and gradually allowed about five pints of this fluid to escape. It was so thick that two hours were occupied in its withdrawal. I then flushed out the vagina with boric lotion and left the tube *in situ*. In the next 12 hours about two pints more drained away. The patient is now going on well, the uterine cavity and vagina being flushed out daily with 1 to 80 lysol solution. I propose to enlarge the opening when the uterus is of normal size.

Stillington, Yorks.

### NOTE ON A CASE OF STRANGULATED INGUINAL HERNIA IN AN INFANT NINETEEN DAYS OLD; OPERATION; RECOVERY.

BY JOHN D. RICE, M.B., B.CH. R.U.I.,

ELTHAM COTTAGE HOSPITAL.

ON the evening of Oct. 27th an infant, aged 19 days, was brought to me by his mother with a lump in his left inguinal region. On examination I found a tense swelling partly filling the left side of the scrotum and the inguinal canal. No impulse could be felt or seen when the child cried. A percussion note could only be considered doubtful, if anything dull. There was considerable œdema, with redness of the skin and subcutaneous tissues. The swelling (which I could not reduce) was also painful and the child cried lustily when touched. As there had been no vomiting or retching and the general condition of the child was good I prescribed an evaporating lotion and told the mother to put the little one to bed and to raise the buttocks on a pillow, as I thought that it might possibly be hydrocele of the cord. The next day there was a marked change for the worse. Vomiting had commenced and bloody mucus in small quantities was passed per anum. Without delay I had the child removed to the Eltham Cottage Hospital and at 6 P.M., after the administration of an anæsthetic, I cut down on the swelling and found a very tight stricture at the upper end of the inguinal canal. When this was divided the gut slipped back into the abdomen; the colour of the intestine though dark was not black. I put in a few deep sutures of silk and closed the wound rapidly, as the patient's condition was becoming alarming. A collodion and antiseptic dressing was applied and the usual stimulants to combat shock were administered. The child rallied well, ceased to vomit, and took the breast vigorously a few hours after operation. Convalescence was uninterrupted, and at the end of a fortnight the little patient was sent home, the wound having practically healed by first intention, and now after nine weeks there is only a fine scar with no bulging even on crying lustily.

I may add that immediately before operation the child was almost moribund, and I warned the parents that the chances were against his surviving the operation (the stricture having then lasted 39 hours and also considering the age of the patient). My best thanks are due to Mr. H. Sandford Smith, who administered the anæsthetic, and to the nursing staff of the Eltham Cottage Hospital for their assiduous care of the infant.

New Eltham.

## A NOTE ON THREE CASES ILLUSTRATING THE VALUE OF SUPRARENAL EXTRACT.

BY WALTER HENRY BROWN, F.R.C.S. IREL.

CASE 1.—A man, aged 53 years, had been for the last 12 months suffering from profuse sweating following on an attack of nephritis. The sweating was so severe that latterly he had to change his clothing two or three times daily. He was passing only about six ounces of urine in the 24 hours. During the year he had lost two stones in weight. For the whole year he had been under treatment, but the sweating persisted and even increased. I put him on suprarenal tabloids. In two days the sweating began to subside and at the end of four days it had entirely ceased. Further, on the fourth day a normal quantity of urine was passed.

CASE 2.—A patient, aged 30 years, a "bleeder," suffered from hæmorrhoids. The bleeding was very severe, often soaking through his clothes, and he was beginning to suffer from the effects of the continuous drain. From the family history it did not seem to be a suitable case for operation, so I put him upon suprarenal extract, with the result that in a week's time the bleeding ceased and it has not yet returned.

CASE 3.—The patient, a woman, aged 36 years, had been much reduced by persistent hæmorrhage from a uterine myoma. Ergot and mineral acids had been tried without benefit; but within 48 hours of her taking suprarenal extract the bleeding ceased.

I record these instances of the power of this animal extract in the hope that my experience may be of benefit to others. In the first case related the patient had been examined by several medical men, but not one had seen such terrible distress in a man who was otherwise quite well. It is interesting to note that the quantity of urine passed increased as rapidly as the sweating diminished.

Leeds.

## GREAT NORTHERN CENTRAL HOSPITAL.

### A CASE OF EXTREME DILATATION OF THE LARGE INTESTINE NOT DUE TO STRICTURE, TERMINATING FATALLY.

(Under the care of Dr. H. W. SYERS.)

THE rarity of idiopathic dilatation of the colon is very great Some of the cases certainly seem to be congenital in origin, while in another group the disease is apparently acquired. We have practically no knowledge of the etiology of the disease. One of the most striking examples of the disease was described by Dr. H. D. Rolleston and Mr. Warrington Haward.[1] Early colotomy appears to be the only treatment likely to be of any use. In a case under the care of Dr. Osler[2] recovery followed colotomy, but that case was congenital in origin.

In December, 1900, a carpenter, aged 59 years, presented himself in the out-patient room of the Great Northern Central Hospital giving a history of discomfort and distension after food during a period of many months. The abdomen was enormously distended and very tense. He was treated as an out-patient for a few days and then admitted to the ward. He had always been in good health until about 12 months before coming to the hospital. At that time he first noticed uneasy sensations after food and a feeling of fulness. He also observed that the abdomen was larger than was formerly the case. At this time he was much troubled with a frequent desire to defecate but without result; these efforts were attended with considerable straining. When the bowels acted the motions were loose, but no blood was passed, neither was the action accompanied by pain. The swelling of the abdomen gradually increased and he was able to work intermittently only. Six weeks before admission he was compelled to leave off work altogether. At this time the swelling sometimes became much less marked, but it always reappeared, the periods of improvement being of short duration only. He had not noticed that the symptoms were in any way influenced by the nature of the diet, and at no period of the illness had he been troubled with vomiting. The patient's previous health had always been good with the exception that he suffered from acute rheumatism in 1871; he had not, however, experienced any further attack. He appeared to have been a free drinker, but there was no history of syphilis. The family history was altogether unimportant. On admission he was thin and wasted but of good colour. He was somewhat short of breath. There was no complaint of pain. The tongue was clean and the pulse and respiration were of normal frequency. The abdomen was uniformly and greatly distended, being also very tense. The percussion note was everywhere resonant and the liver dulness was altogether obliterated. There was no evidence of the presence of fluid in the peritoneal cavity. Over the back of the chest on the left side the abdominal resonance extended to the angle of the scapula; below this point the breath sounds were almost inaudible. The lungs were healthy at the apices and the heart sounds were normal. The specific gravity of the urine was 1016; it was acid and free from albumin. On rectal examination it was found that the anal orifice was drawn up and contracted, the rectum being greatly distended. There was no growth in this locality. The long rectal tube was passed and a very large quantity of gas escaped, its removal giving the patient much relief. After the use of the long tube the abdomen was still distended, but less so than before the passage of the instrument. When the extreme distension was overcome in this way the outlines of the distended intestine could be clearly made out and very marked peristaltic movements were also discernible. No enlarged glands were anywhere to be detected. The patient was ordered a dry diet, the quantity of liquids being restricted as far as possible, and he was kept in bed. No drug treatment had any but the most fleeting influence on the patient's symptoms and physical signs Neither turpentine, nor strychnine, nor belladonna had any effect in permanently reducing the distension, the only relief, and that purely temporary, being afforded by the passage of the long rectal tube. This proceeding was invariably followed by the passage of great quantities of flatus The condition of the patient being unsatisfactory and the possibility of a stricture being in question, Mr. E. C. Stabb was asked to see the patient, and it was agreed that the only treatment likely to be of service was surgical. The advisability of laparotomy being performed was then submitted to the patient, but he absolutely declined operation of any kind and left the hospital just after Christmas, against advice. Nothing more was heard of him until the middle of January, when he again applied for admission. His condition was now very serious. He stated that since leaving the hospital the distension had much increased, causing great distress, and that for some days before his second admission he had been troubled with more or less constant vomiting. His pulse was now rapid and feeble and vomiting of stercoraceous matter was frequent. Immediate operation being deemed necessary Mr. Stabb performed median laparotomy; this revealed an enormous distension of the whole of the large intestine, while the small intestine and stomach appeared to be more or less collapsed, owing, doubtless, to the great pressure upon them exerted by the distended colon. The abdomen, so greatly distended before operation as to appear to cover the body of the patient, was practically filled by the enormously distended large intestine, the abdominal wall being stretched to all but the utmost limit of its capacity. No stricture or other obstruction could anywhere be detected. Colotomy was performed, leading to the discharge of an enormous quantity of gas and to the escape of about two gallons of very offensive fluid fæcal matter. A Paul's tube was tied in. The whole operation only occupied a few minutes and was performed under slight anæsthesia, as the serious condition of the patient prevented his being thoroughly anæsthetised. The patient died the next day from heart failure.

---

[1] Transactions of the Clinical Society of London, vol. xxix., 1896, p. 201.

[2] Archives of Pediatrics, 1893, vol. x., p. 3.

*Necropsy.*—At the post-mortem examination the body was found to be considerably wasted; rigor mortis was well marked. The abdomen was enormously distended, the stomach and the whole of the intestine being dilated to their utmost capacity and showing signs of atrophic catarrh. The transverse colon measured over 15 inches and the sigmoid flexure over 18 inches in circumference. The distended state of the stomach and small intestine differed widely from the condition found at the operation when they were small and collapsed. Doubtless their distension was due to the removal of the pressure of the large intestine when the latter was opened. For the same reason the dimensions of the large bowel during life and before operation were far in excess of the measurements just given. No stricture or growth was found in any part of the intestine large or small. The solar plexus was atrophic; the pancreas was very firm. There were adhesions at both pulmonary apices, otherwise the lungs were healthy except for the presence of œdema. The heart was large and fatty and the aortic valves were incompetent through atheroma. The left ventricle was dilated. The spleen was small and firm; the liver was large and of somewhat granular texture. The gall-bladder was healthy.

*Remarks by* Dr. Syers —This case must be classed amongst those of that extremely rare affection idiopathic paralysis of the intestine. From the article by Dr. W. H. White on the subject in Allbutt's System of Medicine I gather that only 12 such cases have been recorded in 40 years, and that since 1880, during which lapse of time 8000 post-mortem examinations have been made at Guy's Hospital, not a single case has been observed.

As regards the symptomatology in this case it is worthy of note that peristalsis was quite easily observed when the extreme distension had been relieved; no doubt the fact of peristaltic action being only exceptionally noticed was due to the extreme distension of the abdomen. The patient at no time complained of actual pain, but only of discomfort: the latter, however, was often extreme It was in all probability this absence of pain which led him to decline operation, to which, indeed, he was strongly opposed. At no period of his stay in the hospital was there actual constipation; on the contrary, the bowels were always more or less loose. Vomiting was not noticed during his first residence in hospital, setting in late in the course of the illness and becoming stercoraceous at the end. The use of the rectal tube always gave relief which was unfortunately of but very temporary duration.

As to the cause of the condition, it is impossible to speak definitely. The patient on the whole had always been in good health; he had not suffered from indigestion and the action of the bowels had always been regular. It is possible that the condition of the solar plexus may explain the occurrence of the malady. I have mentioned that the plexus was atrophic, and it is possible that this lesion may have led to the production of atony of the whole intestinal tract, but even assuming this mode of causation of the symptoms we remain completely in the dark as to the why and wherefore of the change in the solar plexus. As in so many other "explanations" of the origin of maladies, nothing more is effected than the removal of the difficulty one step further backwards. It should be mentioned that the suprarenal capsules were in a healthy condition.

As regards treatment the futility of the administration of drugs was strikingly illustrated, as it always is in this class of disease It is unfortunate that the patient refused operation when he was in hospital for the first time, as his general condition was then fairly good. From this period his health rapidly deteriorated, and when he again entered hospital an operation could do no more than afford a slender chance of prolonging his life. The case is an extremely unusual one, and its pathology is most difficult, indeed, impossible, according to our present lights, to understand. But on this account it is only the more worthy of record.

My best thanks are due to Mr. A. Whitmore, the house physician, from whose notes the history of the case has been abstracted.

## EGERTON HOSPITAL, PESHAWAR.

### A CASE OF GASTROTOMY FOR REMOVAL OF FOREIGN BODIES FROM THE STOMACH; RECOVERY.

(Under the care of Lieutenant-Colonel G. W. P. Dennys.)

The question of the treatment of foreign bodies in the stomach is sometimes difficult. If there is any chance of their passing into the intestine operation may be delayed until symptoms arise. Feeding with pultaceous food will generally be followed by the passage of the foreign body, but purgatives should be eschewed. The chief reason for operation in the following case was the large number of coins present. A very excellent example of the foreign bodies which can pass through the whole alimentary canal is to be found in The Lancet[1]; in this case a man had been in the habit for 14 years of swallowing stones. On one occasion he claimed to have swallowed nine and a half pounds, and when in the Peterborough Infirmary under the care of Dr. Cane 66 stones were removed from the rectum and 25 more were passed later.

A powerfully-built, healthy-looking, little man, about 30 years of age, came to the Egerton Hospital, Peshawar, on Oct. 20th, 1901, and gave the following extraordinary story. He said that he was an Afghan, that he resided in a village in Afghan territory several marches across the border, and that he was an ardent disciple of a mulla (holy man) who lived in the Peshawar district. He had been in the habit of making periodical visits to this mulla with the object of receiving religious instruction in the Mahomedan faith. Eight days before he consulted Lieutenant-Colonel Dennys he said that he was coming into British territory on a visit to his mulla. On arriving at a place called Dakhi (one march beyond Landi Kotal) he found that all travellers were searched by the Amir of Kabul's order and that all property in their possession, including money, was taxed. He said that a tax of 3 per cent was levied on all cash in the possession of travellers, and that in order to evade this tax he conceived the idea of swallowing all the money he had with him. While some of his companions were being searched he set to work to swallow, as fast as he could, a sum of 65 Kabuli rupees which he had with him. He had nearly completed his wonderful feat when the Amir's officials detected his game and rushed at him. He took to his heels and ran down the road, swallowing as fast as he could as he ran the remainder of the cash, but before he could finish his "meal" he was caught and six remaining rupees (some of which were in his mouth still) were seized by the officials and forfeited. As the patient had 65 rupees to start with, and as six only remained when he was caught, he was satisfied that he had swallowed 59 of the coins. He was, however, allowed to proceed on his journey. On his arrival next day at Landi Kotal he went at once to the small Government dispensary there, told his story, and asked for a strong purgative, which was given to him. This, though it purged him violently, failed to bring away any of his lost treasure. A day or two afterwards another purgative was given, but this was as unsuccessful as the first He then went on to Peshawar (three marches) and related his grievance The cash had then been inside him for eight days. The only symptoms he complained of were a feeling of weight in the stomach and some loss of appetite. His grief over the loss of his money was, however, very acute, and his only thought appeared to be the recovery of his hidden treasure. He wanted Lieutenant-Colonel Dennys to cut him open at once and to restore to him his money.

---

[1] The Lancet, March 18th, 1899, p. 764.

A most careful examination by palpation of the abdomen when the patient lay on the table failed to reveal the smallest sign of the silver mine within him. The intestines were quite empty and the abdominal walls, being free from fat, facilitated the examination. But on making the man stand up and stoop forward and on applying intermittent pressure just above the pubes a moveable heavy mass could be felt most distinctly to come in contact with the tips of the fingers It was, however, quite impossible to make out the size of this mass or to grasp it in any way between the fingers. It seemed just possible that the coins might have passed through the pylorus and have become lodged in a coil of some part of the small intestine, but against this were the facts that the man's bowels had at no time become obstructed and that nothing could be felt in the abdomen when the man was lying down. It was decided to feed him up for 24 hours with large quantities of solid food to be followed with a strong purgative. If this failed to remove the coins it was proposed to make an exploratory incision midway between the umbilicus and the pubes. The purgative acted very freely but not a single coin appeared in the dejecta. On the morning of the tenth day after the man had made his extraordinary and indigestible "meal" Lieutenant-Colonel Dennys decided to operate. By this time the patient's distress had become very acute. He complained of a continuous burning pain in his abdomen which was much aggravated by movement, and the only position which he could maintain for any length of time was sitting in a squatting attitude with his body thrown well forward His pulse was rapid, but there was no rise of temperature.

On Oct. 23rd he was placed under chloroform, the skin of the abdomen having previously been carefully washed and disinfected in the usual way. An incision three inches long was made in the middle line, commencing one inch below the umbilicus, and the peritoneum was opened. On passing two fingers into the abdominal cavity no sign of the heavy mass (so distinctly felt when the man was standing up) could be discovered. *Some coils of small intestine* presented in the wound. With much patience the whole length of the small intestine, from the pylorus to the cæcum, was slowly and gently passed through the fingers, but nothing was found. Lieutenant-Colonel Dennys then inserted his whole hand into the peritoneal cavity and explored the entire length of the large gut from the cæcum to the sigmoid flexure of the rectum, but it was also empty. He then passed his hand up between the coils of intestine and the anterior abdominal wall to the stomach, and he could distinctly feel the whole mass of rupees lying in that organ, dragging by their weight the posterior wall far back into the abdominal cavity It seemed obvious that the stomach could not be opened and its mine of wealth removed through the exploratory incision below the umbilicus, and it was a question whether the patient could stand the shock, prolonged anæsthesia, and further manipulation necessary for a gastrotomy operation. He had already been more than an hour under chloroform The immediate suturing of the lower abdominal incision was imperative This was done as rapidly as possible The peritoneal edges were brought carefully together by eight or 10 interrupted carbolised catgut sutures Four stout silk sutures were then passed through the skin and abdominal muscles, and, finally, some superficial fine silk sutures brought the edges of the skin neatly together. The patient was taking chloroform well, his pulse was *very fair, and there was remarkably little* shock. All through the operation his chest and abdomen and pelvis had been kept swathed in towels wrung out in hot carbolic lotion.

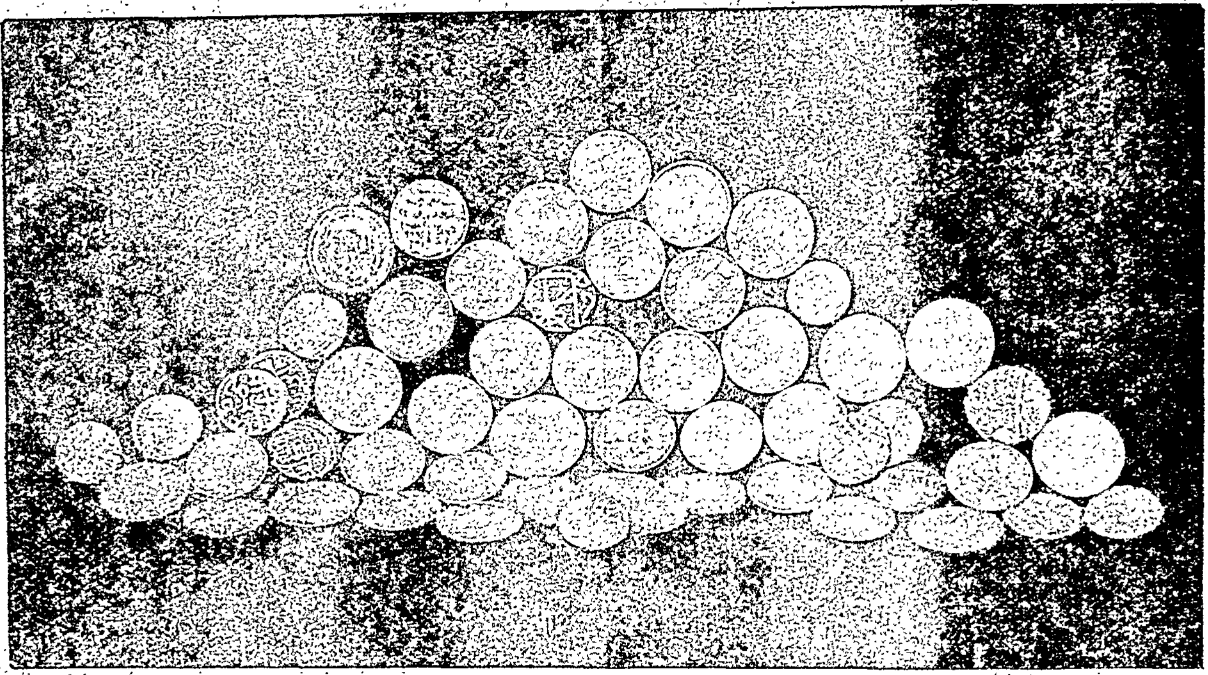
It was now decided to perform a gastrotomy and to remove the coins. The incision recommended by Mr. H. G. Howse[2] was made—i e, an oblique one three inches long, parallel with and one inch below the lower margin of the left costal cartilages and commencing about one and a half inches from the middle line. The muscles and abdominal fasciæ were incised in the same direction as the superficial parts Immediately the peritoneum was opened the lower border of the stomach with the omentum attached bulged into the wound. The anterior surface of the stomach was then drawn gently out, sufficiently to permit of an incision two and a half inches long being made in it. Sponges attached to strings were packed in the sides of the wound to prevent protrusion of coils of intestine, which at this period of the operation were very difficult to restrain owing to the patient making violent efforts to vomit Mr. Allah Jowaya, assistant *surgeon, held the anterior wall* of the stomach firmly in his fingers, and Lieutenant-Colonel Dennys made an incision through the peritoneal and muscular coats in the long axis of the stomach. This caused very profuse bleeding from a number of small arteries and veins which were seized and tied with fine catgut before the mucous coat of the stomach was opened. When the bleeding had ceased the knife was passed through the mucous lining of the organ Several small vessels in this coat began to bleed profusely; these were seized with Spencer Wells forceps. Lieutenant-Colonel Dennys then inserted his index and middle fingers into the stomach as far as they would go, but failed to find the coins which were lying out of reach at the back of the abdominal cavity. Owing to the extreme elasticity of the stomach wall no difficulty was found in inserting the whole of the left hand through the incision into the interior of the stomach. This procedure was preferred to groping about at the back of the viscus with a pair of forceps which might have pinched or injured the mucous membrane. Once the hand was inside there was no difficulty in gathering up the large number of coins that lay therein. The operator had, however, to insert his hand a second time before the whole of the coins could be removed. The patient began to strain and vomit again after the coins had all been extracted, and it was impossible to attempt to suture the stomach walls till the vomiting had ceased. The mucous coat showed a strong tendency to curl inwards along the incised edges, and it was with much difficulty that Lieutenant-Colonel Dennys was eventually able to bring the edges neatly into apposition with catgut sutures When this had been done catgut Lembert's sutures were applied to the peritoneal lining, and after satisfying himself that the incision was firmly closed and that all bleeding had ceased Lieutenant-Colonel Dennys returned the protruding portion of the stomach into the abdomen. The abdominal incision was then sutured in exactly the same way as the incision below the umbilicus The external wounds were dusted with iodoform, covered with dry antiseptic gauze, over which a thick pad of sal alembroth *wool was placed, and the patient was* removed to his bed and packed round with hot-water bottles He rapidly rallied from the slight shock caused by the operation and it was extremely difficult to restrain his exuberant joy at the news that his lost treasure had been safely recovered

On the second day after the operation his temperature rose to 99 4° F, and on the evening of the third day it was 100°, after which it never again went above normal The lower abdominal wound healed beautifully by first intention without a drop of pus, but the upper wound did not heal so well, and owing to a small collection of pus having formed under the skin a drainage-tube had to be inserted for a few days and the patient was fed by nutrient enemata three times a day for the first six days consisting of yelks of eggs, milk, and brandy He complained a good deal of thirst during the first two or three days, for which small lumps of ice were allowed by the mouth from time to time On the sixth day he was allowed a small quantity of milk every two or three hours On the eighth day he was given soup as well as milk, and on the tenth day he was promoted to milk, rice, butter, and soup.

---

[2] Dictionary of Practical Surgery, p 590

The patient was a wild trans-border Pathan and could not be made to understand the danger of the operation which he had undergone. It was only by placing a man on duty over him night and day and keeping a watchful eye on him constantly that he could be prevented from tearing off his dressings and getting up. He admitted on the sixth day that he had stolen and drunk a pint of milk two hours after the operation which the dresser on duty had left on a small table and which was intended for administration by the rectum. But apparently no evil resulted from this rash act on his part. For the first three days it was found necessary to keep him more or less deeply under the influence of morphia by hypodermic injection owing to the impossibility of keeping him quiet otherwise.



Reproduction of a photograph of the coins recovered from the patient's stomach.

The actual coins found in his stomach were 55 Kabuli rupees (see Figure). The patient was very indignant when told that only Rs.55 had been found inside him, for he contended that he had swallowed 59, but he afterwards admitted that he might have dropped some when he was being chased by the Amir's officials. The exact weight of these 55 Kabuli rupees was found to be 17¾ ounces.

*Remarks by* Lieutenant-Colonel DENNYS.—The above case deserves to be recorded, not only on account of its surgical interest, but because of the extraordinary and, I believe, unique circumstances which led to the necessity for so serious an operation.

The most interesting points in connexion with this case may be summed up as follows. 1. The weight of the coins in the stomach when the patient was standing up dragged the lower portion of the stomach down almost into the pelvis, and the moveable mass which I could feel just above the pubes led me to believe that they had become lodged in some mysterious way in a coil of the small intestine without causing obstruction of the bowel. 2. The remarkable absence of any serious symptoms till the tenth day after the coins had been swallowed. 3. The extraordinary vitality of these wild frontier people and their power of resisting shock. This patient was two and a half hours under chloroform, four and a half ounces of the drug had been used through Junker's inhaler, the whole of the large and small intestines had been freely handled, many feet of gut had prolapsed through the wound when he was vomiting and were returned with no small difficulty, the stomach had been opened and my hand had been introduced into that organ, and yet at the end of the operation the patient had a very fair pulse and no shock worth mentioning. 4. The story which the patient gave of his having swallowed a pint of milk two hours after the operation when the dresser was out of the room. The stomach never after the operation showed the slightest tendency to be irritable. 5. The rapid and almost uneventful recovery of the patient who but for the suppuration that took place in the upper wound was practically quite well 10 days after the operation. The suppuration of the upper wound I attributed to the patient having inserted his fingers under the bandage and dressings to ascertain what sort of an incision I had made. He admitted having done this. The man's great terror all the time he was under my treatment—and nothing I could say would allay his fears—was that after all I had done for him I was sure to insist on his becoming a Christian.

On the fourteenth day after operation the man was in excellent health, able to eat anything, and left the hospital for his home on the twentieth day.

# Medical Societies.

## HARVEIAN SOCIETY OF LONDON.

### *Exhibition of Cases.*

A MEETING of this society was held on Dec. 19th, 1901, Dr. H. A. CALEY, Vice-President, being in the chair.

Dr. E. CAUTLEY showed a case of Infantile Scurvy Simulating Acute Epiphysitis. The patient, a female, was born on Dec. 13th, 1900, and came under observation on Dec. 2nd, 1901. She was the fourth child. Two children had died in infancy from diarrhœa. The patient was fed on cow's milk and barley-water during the first two months of life and since then on condensed milk and barley-water, with the addition of "Brighton biscuits" at the age of five months. The history of the dietary was not very trustworthy. The left arm and shoulder had been swollen for two weeks. The child was pale and ill and she cried when moved or touched. Four teeth were cut and the two upper lateral incisors showed signs of eruption. The lower gums were normal but the upper gums, round the teeth, were swollen and dusky red in colour. There was extensive swelling of the left shoulder, extending half way down the upper arm. The swelling seemed to be in front of the joint and under the periosteum of the humerus. There were moderate signs of rickets—beaded ribs and enlargement of the epiphyses, especially of the knees which were much swollen above the condyles and very tender. Exploration of the shoulder confirmed the diagnosis of scurvy, pure blood being obtained. In the course of two days the swelling extended downwards to the elbow. The child made a satisfactory recovery under anti-scorbutic diet, without drugs, but still presented considerable thickening of the left humerus, especially of the lower half. Pyrexia was slight and irregular.—Dr G. A SUTHERLAND suggested the possibility of fracture.—Dr. CALEY remarked on the rarity of the condition. He thought that a series of skiagrams in such cases would prove of interest.—Dr. CAUTLEY, in reply, pointed out that at first the swelling only extended as low as the middle of the humerus and that in the course of two days it extended down to the lower epiphysis. The gradual extension downwards was not in favour of fracture and there did not appear to be any bending of the bone He pointed out that the thickening was most marked in the lower half of the humerus by reason of absorption taking place from above downwards, the blood last effused being the last to be re-absorbed.

Mr. F. JAFFREY showed a child, aged 10 weeks, with Craniotabes. When first seen a month previously the child was suffering from congenital syphilis, and on examining the skull he was found to have craniotabes, which practically affected all the bones of the vertex, but was best marked on either side of the lambdoid suture. The child was at once weaned and put on grey powders and small doses of cod-liver oil. Mr. Jaffrey made a few remarks on the causes of craniotabes and said that the best marked cases he had seen were in subjects of congenital syphilis, though he had seen the condition not uncommon in rickets.—Dr. L GUTHRIE pointed out that many cases improved very rapidly, even as rapidly as the one brought before the society. He believed in the association of the affection with congenital syphilis, but had seen cases in ill-developed infants independently of either congenital syphilis or rickets.—Dr. CAUTLEY thought it important to have a clear understanding as to what was meant by the term "craniotabes" He considered that there were several varieties of the affection. One he regarded as due to delayed development. The bones of the vertex were sometimes not ossified at birth and remained membranous for some weeks. This was especially the case in premature infants, but it occurred also in infants born at full time. He thought that the present case was one of delayed ossification. To a second variety he gave the name, the "parieto-occipital type." It was characterised by softening along the sutures, mainly the lambdoid suture. This, he said, was extremely common in infants brought up on condensed milk, and especially so when the infant was kept in close, badly ventilated rooms Consequently it was found most often in the early months of the year. He ascribed it to a deficiency of the lime salts in the food. The text-book type, that in which scattered isolated spots of softening were found, he regarded as extremely rare, and he had never seen a case during life and verified post mortem. He had also seen very extensive craniotabes associated with congenital cerebral defects and with congenital hydrocephalus He was extremely sceptical as to any etiological association with congenital syphilis, beyond the general malnutrition so often present in this disease.—Dr. W. EWART discussed the tendency to primary atrophy of the tissues in connexion with congenital syphilis, and suggested that the presence of an analogous process in other bones would be confirmatory of the view that the disease was a cause of craniotabes.—Dr. SUTHERLAND thought that the question was not yet settled and that the book type of the affection was not very rare, especially in the parieto-occipital region He believed those cases to be due to congenital syphilis when the patches were circular with surrounding ossified bone. As to the mode of production, he thought that in some cases absorption took place from the outer surface of the bone.—Dr. CALEY suggested that in view of the possibility of a connexion with congenital syphilis it might be advisable to treat all such cases with mercurial preparations.—Mr JAFFREY replied shortly.

---

## LIVERPOOL MEDICAL INSTITUTION.

*Exhibition of Case.—Fracture of the Fifth Metatarsal Bone.—Coxa Vara.—A Speedy Method of Removing the Pain of Piles.—Anæsthetist and Operator.*

THE fifth ordinary meeting of the session of this society was held on Dec. 19th, 1901, Mr. EDGAR A. BROWNE, the President, being in the chair.

Mr. T. H. BICKERTON showed a patient with Melanotic Sarcoma of the Conjunctiva.

Mr ROBERT JONES related: 1. Five cases of Fracture of the Fifth Metatarsal Bone due to direct violence. Although no reference to this fracture was found in the text-books he thought that the lesion was common. Radiographs of each case were shown and the fracture was found to be almost at the identical spot in each case, just below the base of the fifth metatarsal bone. The injury in each case was due to the body-weight acting upon the foot when in the position of equino-varus, and was evidently due to a cross breaking strain, the bone yielding close to the very strong ligaments which bound the metatarsal base to its surroundings The symptoms of the fracture were pain over the site, a little swelling, no crepitus, and pain on attempting to invert the foot 2. A series of cases of Coxa Vara, illustrating the bilateral infantile type and contrasting it with the changes in the neck usually present in extreme rickets. Mr Jones also showed the adolescent type, which in one instance was very extreme, the rounded head being enlarged, its lowest portion reaching three-quarters of an inch below the acetabulum. The skiagram distinctly explained the very marked limitation in movement which gave the patient great pain. It presented a very rare appearance. The head of each femur was opposite to the acetabulum, and the neck formed an acute angle to the shaft. The trochanters were not thickened. Three and a half inches from the top of the trochanter the lower border of the femoral head on the left side was within a quarter of an inch of the shaft. Part of the rounded head was excurvated out of the acetabulum towards the femoral shaft. The neck was irregular and somewhat narrowed in contact with the head The upper border of the left neck measured three and a half inches and the lower three-quarters of an inch. On the right side the head practically touched the shaft four and a half inches from the top of the trochanter. The superior border of the neck was four and a half inches in length and the lower one and a quarter inches. The same kind of irregularity was noted and the neck was very thinned towards the femoral head The head seemed also to be levered out of the joint.—The etiology and treatment were discussed

Dr. WILLIAM CARTER read a note on a Speedy Method of Relieving the Pain of Piles A suddenly protruded pile which caused extreme pain, the intensity of which was not diminished by a prolonged external use of several much-praised remedies, was almost immediately and permanently relieved by a single application of 10 cubic centimetres of cocaine and 20 cubic centimetres of menthol in oil of theobroma These were made into a cone which was rubbed over the part

Mr. A BURNS GEMMEL read a paper entitled "Anæsthetist and Operator," in which he stated that charges had been made against those engaged in the administration of anæsthetics of "want of knowledge and want of care," and that surgeons at the same time objected to anæsthetists claiming to be "supreme in their own place" and maintained that the surgeon should be master over the management of the anæsthetic as over every other detail of the operation. Medical men engaged in the administration of anæsthetics were divided into (1) those under direction and bound to obey orders, such as the medical student and the house surgeon; and (2) those who, recognising the great responsibility of the work, undertook it and therefore ought not to be interfered with in any way in the performance of their duty. The duties of the anæsthetist and the operator were briefly considered, and it was pointed out that each ought to give his whole attention to his own work. In the event of a fatality each for his own work was accountable (1) to his conscience, (2) to the relatives and friends, and (3) to the coroner and jury. Friends and relatives knew that the surgeon came to operate and in the event of disaster from the anæsthetic would blame the anæsthetist Young surgeons did not administer to the extent to which they did before the special anæsthetist came into existence and the older surgeons had ceased to administer. Seeing numerous cases merely as an operator did not give experience of anæsthesia and therefore the surgeon, old or young, had no right to dictate to the administrator. The special anæsthetist was only available for hospital patients and the richer portion of the community, consequently the greater part of this work was undertaken by the general practitioner who fully recognised his responsibility, and any attempt to deprive him of this responsibility and to lay it on the operator would tend to make him less careful and therefore less skilful He (Mr. Gemmel) was always ready to do whatever the operator wished if it could be done with safety, but he strongly objected to the assumption of the right to "dictate" by the operator. He who did the work must bear the responsibility, and he who bore the responsibility must be allowed to do his work without interference.—Dr. H. BRIGGS said that Mr. Gemmel might have saved himself a great deal of trouble and have avoided the useless discussion which was to follow by pointing out who was to be supreme authority or "captain of the ship" if not the operating surgeon.—Dr. WILLIAM ALEXANDER said that in the coroner's court the responsibility for the anæsthetic was distinctly thrown upon the operating surgeon. The patient selected his surgeon, left himself in his hands, and looked upon the anæsthetist as an assistant to the operator. In cases where the family medical attendant administered he had to bear the brunt of the disagreeable things said or thought by the relatives and so interposed between them and the surgeon, but even then the case was considered by them as a fatality in the practice of the operator. As a general rule the preliminary arrangements for the administration were agreed upon between the surgeon and the anæsthetist, but if there were any difference of opinion the surgeon should carry the day. In the present day patients often thought more of the danger of the anæsthetic than of the operation, and if this fear continued probably it might arrive at such a pitch that the patient would select his favourite anæsthetist first and leave him to call in the surgeon as the junior. Until that occurred the surgeon should lead the way. The surgeon would incur a grave responsibility if he asked the anæsthetist to give more anæsthetic when the latter declared that it would be dangerous to give more. In all cases the anæsthetist and the surgeon should stand shoulder-to shoulder, bearing the responsibility together and standing up for each other.—Mr. F. T. PAUL thought that the responsibility in regard to all preparatory treatment must generally rest between the practitioner and the surgeon. The choice of the anæsthetic in certain cases must lie with the surgeon. Responsibility in fatal cases would vary with the circumstances. When the death was entirely due to the anæsthetic the anæsthetist was naturally responsible; when entirely due to the operation the surgeon was. But in Liverpool it was customary to hold the surgeon responsible to the public. Practically friction between the surgeon and the anæsthetist was unknown in Liverpool, and very little give-and-take would render any such contingency impossible.—Mr. F. W. BAILEY was convinced that operator and administrator must work together dependently and not independently; they must coöperate. In cases of doubt or gravity in the course of the administration an opinion would be courted and none was better able to give it than the operating surgeon The operator and the anæsthetist were likened to a tandem team, each doing his share of the work dependently and to the best of his ability.—Sir W. M. BANKS said that after hearing the paper he was only the more strongly confirmed in the view that in the conducting of an operation there must be some one person in supreme command and that person must be the surgeon. The surgeon's position was compared to that of a general. A defeat was associated with the name of the general, however much it might have been caused by the fault of a subordinate In the case of a death from an anæsthetic it was the surgeon who had to bear the brunt of the odium, because his name was generally more widely known to the public than was that of the anæsthetist. As regarded legal responsibility the Liverpool coroner had stated that he regarded the surgeon as being answerable for all that occurred during the progress of an operation. With reference to the preliminary arrangements it was important to note that the surgeon had almost invariably seen the patient before the operation and necessarily knew something about his position, while the anæsthetist (unless he were also the medical attendant) saw him for the first time. If a patient during an operation were dying from hæmorrhage the anæsthetist might logically say that that was none of his business, but if the patient were dying, say, from some vomited matter sticking in his larynx, dare the surgeon say that he was not concerned with that and refuse to do a tracheotomy? Were an equal dual control established difficulties of a very serious character might occur. So far, maintaining these opinions as he had always done, he had never had on any occasion any difference of opinion with the anæsthetist, but he felt certain that but for his own supervision he would not have seen two deaths out of some 11,000 or 12,000 cases, but more likely 20. So far from producing harmony at an operation Mr. Gemmel's views would tend to produce discord and a sense of mutual distrust between operator and anæsthetist. But, after all, the whole discussion was purely an academical one—Mr. DAMER HARRISSON, Mr. G. G. HAMILTON, Dr. T. R. BRADSHAW, Mr. G. P. NEWBOLT, Dr. A. S. F. GRUNBAUM, and Dr. NATHAN RAW also spoke, and Mr. GEMMEL replied.

---

# EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

## *Exhibition of Cases and Specimens.*

A SPECIAL clinical meeting of this society was held on Dec. 18th, 1901.

Mr. C. W. CATHCART exhibited a patient after Drainage of Both Pleural Cavities for Double Empyema. The boy, aged 15 years, had double pneumonia in January, 1900. On about the sixteenth day 25 ounces of pus were aspirated from the left pleural cavity. On the eighteenth day Mr. Cathcart aspirated about the same quantity of pus from the right pleural sac and three hours later under local anæsthesia and a whiff of ether excised a portion of rib and drained the left side. Four days later 36 ounces of pus were aspirated from the right side and in three days—i.e , a week after draining the left side—he drained the right pleural cavity in a similar manner. The patient was out of doors with both wounds healed on March 13th. His health was now excellent, expansion on both sides being quite satisfactory. The pus contained a pure culture of the pneumococcus. The factors aiding this satisfactory result were the youth and previous good health of the patient, the exclusion by careful precautions of any organisms other than the pneumococcus, and the vigorous and frequent use of inflation by the patient. A great deal of trouble was taken in trying to get Duncan's syphon arrangement to act in keeping up negative pressure in the pleural cavity, but while it drew off the pus it failed in its primary object of producing a *vis a fronte*.

Dr. W. ALLAN JAMIESON showed: 1. A case of Lupus Vulgaris treated at the London Hospital by Finsen's Light Treatment. The patient was a man, aged 28 years. When a child he struck his chin against the edge of a table and in the bruise so produced lupus developed He was treated by various methods by Dr. Jamieson, but in July, 1900, there was still a patch two inches long by one in vertical height of lupus persisting. He went to the London Hospital by his (Dr. Jamieson's) recommendation and was treated for five weeks there by Dr. J. H. Sequeira in September. Considerable improvement followed, but by July, 1901, the condition was as bad as before. He was then treated regularly till October, having had 55 exposures in all. The whole surface was now smooth and almost normal and so far no nodules had reappeared. 2. A case of Rodent Ulcer treated by the X Rays and apparently cured. The patient was a healthy country woman, aged 41 years. Three years since a small papule appeared on the left temple; it was itchy and was scratched. It gradually extended, became crusted, and a second patch formed alongside. When seen in September, 1901, there were two continuous patches of rodent ulcer, implicating the skin alone, and each rather larger than a florin. They were granular and crusted and had the typical rolled edge. For three weeks they were treated by the x rays alone, but the patches were then thoroughly scraped and on the next day they were cauterised with chromic acid fused on a probe to a bead. The surface was then dressed with Beiersdorf's zinc ichthyol salve muslin till it was healed and then the exposures to the rays were resumed. At the same time the margins were gently scraped twice and on the latter occasion they were also touched with nitric acid. Under the rays the disease melted away, so that in the middle of December there was a soft healthy normal integument over all the previously diseased areas. She had a 10-minutes' exposure four times a week There could be no question here of the curative effect of the x rays.

Mr. ALEXANDER MILES showed: 1. A patient after operation (Gastro-enterostomy) for Severe Hæmatemesis. The patient was a woman, aged 42 years, who on Sept. 8th last was suddenly seized with severe hæmatemesis. Four years previously she had been treated by Dr. Robert Stewart for dyspepsia, and the stomach, which was dilated, had been frequently washed out. She had never vomited blood nor did she exhibit any of the ordinary signs of gastric ulcer.

After this attack she regained her normal health and remained well until Sept. 8th, when the hæmatemesis occurred. The usual methods of treatment were unsuccessful in arresting the bleeding which continued for three days. As the patient's life was endangered an operation was advised and it was carried out in the Royal Infirmary on Sept. 10th. On opening the abdomen by a mesial incision and examining the stomach a densely indurated ulcer of about the size of a five-shilling piece was found close to the pylorus. It extended to the lesser curvature and fully two-thirds of the way to the greater curvature. It was therefore impossible to invaginate it without great risk of occluding the pyloric orifice, and the condition of the patient did not justify an attempt being made to excise the ulcer. It was therefore decided to perform a posterior gastro-enterostomy. After opening the stomach its interior was explored with the finger. No definite bleeding point was recognised in the ulcer. The communication between the stomach and the intestine was then completed with silk stitches. Before closing the abdomen about two pints of saline fluid were introduced into the peritoneum. During the first 24 hours after operation rectal injections of saline fluid were given every four hours and frequent nutrient enemata, which were all retained. The foot of the bed was raised. Although she continued to vomit bile-stained mucus at intervals there was no further loss of blood. Flatus was expelled in the evening. On the 12th the patient was better, though there was still sickness occasionally, but this became less frequent when the foot of the bed was lowered. On raising the head of the bed vomiting ceased entirely. On the 13th beef-tea and peptonised milk were given per os. She made an uninterrupted recovery, being up on the twenty first day and she left the hospital on the twenty-ninth day. Since then she has remained well. 2. A patient after operation for Intestinal Obstruction due to Tuberculous Peritonitis, with subsequent development of tuberculous pleurisy which was treated by drainage. The boy, aged 16 years, was admitted to Leith Hospital on August 19th, 1898, suffering from intestinal obstruction. Three weeks previously he had begun to complain of sickness and vomiting and irregular constipation and these symptoms lasted for about a week and then passed off. Three days before admission he was suddenly seized with pain in the abdomen. The pain was not severe and was not localised. He vomited everything that he took. The bowels did not act and no flatus was passed. On admission the abdominal walls were retracted and did not move with respiration Peristalsis was visible in the middle of the abdomen and in both flanks and suggested movements of both large and small intestines. No definite swelling could be palpated. In the right iliac region and in the line of the descending colon marked gurgling was elicited. The abdomen was uniformly tender all over. The rectum was empty and "ballooned." Several enemata were administered without effect. At 8.30 P.M. the abdomen was opened in the middle line below the umbilicus. The small intestine when exposed was distended, deeply congested, and thickly studded with miliary tubercles, as was also the parietal peritoneum. A fibrous band was found to constrict the small intestine a little to the right of the umbilicus. The collapsed bowel beyond the constriction was lying at right angles to the distended bowel and the two loops were united by recent adhesions for about an inch. After dividing the band and separating the adhesions the intestinal contents instantly passed into the collapsed bowel. The whole of the peritoneum was covered with tuberculous nodules but there were no further adhesions. A Keith's tube was introduced into the pelvis and the abdomen was closed For the next five weeks the patient continued to improve, and then the temperature began to rise and the boy complained of pain in the epigastrium and in the right side. These pains became more severe and "catching" and a loud, rubbing, creaking friction sound was heard over the front of the right side. The right base behind was absolutely dull. On Oct. 11th (18 days after the temperature began to rise) a portion of the eighth rib was excised in the posterior axillary line. On opening the pleural sac numerous recent adhesions were found between the chest wall and the lung and clear fluid with some flakes escaped The pleura was closed with catgut sutures and the external wound was closed without drainage. The physical signs gradually cleared up and the patient slowly recovered During the last three years he had enjoyed excellent health and had done his ordinary work as well as taking part in athletics 3 A patient after Excision of the Rectum by Kraske's Method. A labourer, aged 52 years, was admitted to Leith Hospital on Sept. 7th, 1901, complaining of increasing constipation during the preceding six months; his motions were tape-like and streaked with blood. He complained of feeling a lump permanently in the rectum with constant tenesmus. Griping pains across the lower part of the abdomen were present There was also difficulty in passing urine. On examination per rectum a tight stricture within one and a half inches of the anus was found which admitted only the tip of the finger. The edges were hard and ulcerated. The rectum was moveable except anteriorly, where it appeared to be attached to the prostate gland. On Sept. 12th a vertical incision was made from the middle of the sacrum to the anus The coccyx and lower part of the sacrum were removed. The rectum was exposed and isolated, clamped above the tumour, and cut across. The peritoneum was opened in clearing the bowel and was stitched with silk. The rectum was dissected out down to the anus. It was found to be adherent to the prostate, but the disease did not apparently infiltrate that gland. The cut end of the bowel was stitched to the upper angle of the wound and the rest of the wound was loosely sutured and iodoform gauze packing was introduced between the sutures The patient made an excellent recovery. He had not complete control of the bowels, but could keep himself comfortable and clean so long as the motions were solid and he was aware when the bowels were about to move.

Dr. W. G. SYM exhibited a patient, both of whose Lacrymal Sacs he had excised. This had been done for two reasons—viz., on account of impervious stricture with chronic abscess of the sac and long-standing fistula, a condition which gave the patient much distress; and on account also of the fact that in one eye he had a cataract ripe for extraction. Dr. Sym briefly pointed out the dangers of extraction in presence of a lacrymal stricture and showed how by means of removal of the sac these had been avoided and a good result secured. At the time of the first operation a cultivation experiment revealed abundance of pyogenic organisms and the extraction had therefore been postponed for a month; at the end of that time another cultivation from the conjunctiva proved sterile and the extraction was then successfully carried out. The cosmetic result was excellent and the patient was entirely freed from the troublesome lacrymation and discharge.

Mr. HAROLD J STILES exhibited: 1. A boy, aged six and a half years, after operation for Recurrent Tubercle and Stricture following amputation of the penis for tuberculous disease of the glans. In July last the patient had a deeply-excavated ulceration of the glans penis involving the meatus. The inguinal glands were only slightly enlarged Local treatment being ineffectual the penis was amputated. Three weeks before the boy returned to hospital with an aggravated stricture, the result of the recurrence of the tubercle in the stump. The tuberculous and cicatricial tissues around the stump were removed, the scrotum was split, and the penis was re-amputated at its root. The corpus spongiosum was dissected back as far as the perineum and the part in front of the bulb was removed. The bulb itself was then divided longitudinally on the ventral surface and the edges were united to the posterior part of the perineal wound about one and a half inches in front of the anus. The remainder of the wound was closed and infiltration of urine was prevented by the introduction of a catheter into the bladder and the use of Mr. Cathcart's "Sprengel pump." Mr. Stiles said that it would be desirable to remove the testicles, but thought that this should not be done until a few years after puberty. As regards the cause of the condition it was mentioned that the patient had been circumcised, but that the glans and prepuce did not become diseased until three years later. 2. A child, aged 14 months, after operation for Congenital Stricture of the Anus. The stricture admitted only a No. 6 catheter The usual operation was done—viz., the removal of skin around the orifice along, with separation of the mucous membrane and the suturing of it to the edges of the skin wound. The interest of the case lay in the fact that five plum-stones and one shirt-button were removed from the rectum 3 Four cases showing the results of treatment of Congenital Wry-neck by the "open operation." The patients had all been operated upon from 12 to 18 months previously. In each a very satisfactory result had been obtained. Mr. Stiles drew attention to the importance of dividing all the clavicular as well as the sternal fibres of the muscle, in addition to all the fascial bands in front of the depressor muscles of the hyoid bone and the outer part of the internal jugular vein. He preferred a transverse to a vertical incision, as the former gave better access to the deeper structures and the resulting cicatrix was less evident. In his opinion it was quite necessary to excise the lower two-thirds of the sterno-mastoid muscle as recommended by Mikulicz. If the simple open division were done thoroughly a perfectly satisfactory result was obtained without the subsequent use of any apparatus or gymnastic exercises.

Mr. **Alexis Thomson** showed a female patient, aged 52 years, the Pyloric Portion of whose Stomach he had Removed for Cancer three and a half years ago. The patient had suffered from gastric symptoms for nine months. There was a freely moveable tumour above and to the right of the umbilicus. There was no free hydrochloric acid in the gastric contents. The pyloric portion of the stomach was excised by Kocker's method. The tumour, as large as a fist, was a columnar epithelioma projecting into the interior of the stomach but causing no obstruction. Enlarged glands were removed from both curvatures, but they were found to be free from cancerous infection. The patient had since enjoyed perfect health.

Mr. F. M. **Caird** showed a patient after operation for High Shoulder due to an Osseous Plate which had developed between the scapulæ and the vertebral spines.

The following specimens were shown:—

Mr. **Miles**: (1) A Rectum Excised for Malignant Disease by Kraske's operation; (2) specimens of Preputial Calculi; and (3) specimens illustrating Fracture-dislocation of the Spine.

Mr. **Caird**: (1) Specimens and photographs from a case operated upon for High Shoulder; and (2) Carcinoma of the Transverse Colon from a case of Resection and Primary Suture.

---

**Royal Academy of Medicine in Ireland.**—A meeting of the Medical Section of this society was held on Dec. 13th, 1901. In the absence of the President (Sir C. Nixon) the chair was taken by Dr. Walter Smith.—Dr. J. M. Finny exhibited a girl, aged 22 years, with all the typical symptoms of Disseminated Sclerosis. Four years ago, at the age of 18 years, she became completely paralysed as to motion in the arms and legs, with loss of control over the bladder and rectum, and with the formation of large bedsores on the sacrum and the nates. No cause could be found for her illness. She was a patient for 15 months in county Roscommon Infirmary under the care of Mr. E. T. Blakeney, and she left that institution so far recovered as to be in much the same state as that which she now presented. Having called attention to the rarity and peculiarity of this invasion of the disease, and having commented on the variability of its course and progress and the difficulties which such variability produced in the diagnosis of disseminated sclerosis in its earlier stage, Dr. Finny pointed out the signs which were typically demonstrable on the patient, taking them *seriatim* and in the order of their prominence. One of these was a notable complacency with her sad lot and a cheerful contentment with her surroundings, a feature laid stress on by Gowers as being very characteristic of disseminated sclerosis, more commonly met with in females. Mention was then made of the following organic nervous diseases which more or less closely might simulate one or more of the salient features of disseminated sclerosis: paralysis agitans, general paralysis, mercurial tremors, syphilitic diseases, ataxic paraplegia, intracranial tumours, especially of the cerebellum, and transverse myelitis, and although the subject of diagnosis was not entered on or discussed a warning was thrown out as to the risk of confounding it with hysteria, not when all the typical symptoms were present, as in Dr. Finny's case, but when they were ill-defined and varied in extent and gravity under the influence of time.—Dr. George J. Peacocke read a paper on Hemichorea and Parotitis Complicating a case of Diabetes. The patient, a man, aged 64 years, was admitted to the Adelaide Hospital on April 29th, 1901, suffering from diabetes. He presented the usual symptoms—loss of flesh, great thirst, and polyuria. The quantity of urine passed in the 24 hours varied from three to five pints, and quantitative analyses gave 2·7 ounces of sugar on May 2nd and somewhat smaller quantities on subsequent occasions. He continued very drowsy throughout his illness; at times the condition almost approached coma, and he died on May 28th, just four weeks after admission. On May 4th he developed left-sided hemichorea which resisted treatment with hyoscine, bromides, and chloral. Arsenic in 10-minim doses was given as were 20 grains of trional at night Improvement rapidly followed and all the symptoms of chorea disappeared on May 13th. The second complication, parotitis, first made its appearance on May 11th. At first it gave rise to little trouble, but on May 16th there was some elevation of temperature and the parotid gland became painful and tender. The fever continued until the patient's death, but it never reached a higher point than 101·6° F. The cause of the parotitis was quite obscure, and though a similar condition had been described in a variety of diseases and injuries of the abdominal organs so far its occurrence in the course of diabetes had not been recorded.—Dr. Smith, Mr. H. G. Croly, and Dr. A. R. Parsons discussed the paper.—Dr. W. R. Dawson read a paper on Glycosuria and Insanity (a Clinical Study). Cases of glycosuria associated with insanity were of two classes—those in which the insanity was secondary and those in which the glycosuria was secondary, the first being rare. He had had one case of the first class under his care, that of a woman who had suffered for many years from polyuria and recurrent melancholia, with general delicacy, the melancholia being of the type described as characteristic of diabetic insanity. She had been admitted for a severe attack, and sugar being present in the urine she was put on diabetic diet. The sugar and the mental symptoms disappeared and she was discharged recovered in about two months. The diet had since been persisted in and she had remained unusually well for about a year. Other cases were then briefly described which probably belonged to the second class.—A discussion followed. Dr. Smith, Mr. R. Leeper, and Dr. Hayes took part and Dr. Dawson replied.—Mr. J. Burgess read notes of an uncommon case of Sudden Death. He said: The case which I bring forward is one of sudden death from what I take to be a combination of circumstances which are uncommon. The specimen before you was taken from the body of a poorly nourished man, aged 35 years, a labourer out of employment. From the evidence at the inquest I learned that he did not complain of being unwell until the fatal seizure came on. I presume that whilst seeking for employment he was noticed by some people to fall suddenly with his shoulder resting against a wall and then to drop to the ground. The people did what they could to revive him, but when the ambulance arrived he was evidently dead and they took him to the morgue instead of to one of the hospitals. The body was, I remarked before, not well nourished, but it was not emaciated; both lungs were emphysematous with a large amount of muco-pus in the bronchial system, but nowhere were cicatrices exhibited nor was there consolidation. The pericardium was distended, on opening which somewhat over a pint of fluid blood and clots exuded. Both ventricles, especially the surfaces of the right ventricle, were covered by recent lymph, which at the time could be easily detected, and presented a fluffy appearance. Before removing the heart I searched assiduously for the source of the hæmorrhage but without result, nor could I find it afterwards. On opening the heart the valves were found to be in no way affected, the entire ante-wall of the right ventricle was principally composed of fat, and there was almost a total absence of muscular fibre; this was very striking on comparing it with the left ventricle, which was fairly normal. Both coronary arteries were permeable. In the right ventricle was a clot which formed at the time of death. Both auricles presented nothing abnormal. The aorta showed considerable evidence of atheroma. Although I have not been able to demonstrate the source of the hæmorrhage I think that the cause of death is obvious. During an attack of acute pericarditis, associated with a previously diseased heart, a bleeding occurred sufficient although small in amount to cause by its presence fatal paralysis. I find on consulting the literature on the subject that hæmo-pericardium is produced by two sets of causes, the most common being the rupture of the left ventricle of an aneurysm or of some vessel into its sac. The second is that in which during the course of pericarditis of cancerous or tuberculous origin a bloody serum is exuded into the sac, and a similar effusion occurs also in some cases of scurvy and purpura. In my case there was no trace of malignant disease or of tuberculosis, but it owes its interest as one of acute pericarditis with the very uncommon complication of a true hæmorrhage, probably from capillary vessels, which, although comparatively small, was sufficient on account of the diseased condition of the myocardium to cause sudden death.—Dr. Finny did not agree with Mr. Burgess's opinion that the change in the ventricle was due to fat. He suggested a new growth of some description as being more probable.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held on Dec. 18th, 1901, Dr. J. G. Douglas Kerr (Bath), the President, being in the chair.—Dr. S. D. Clippingdale read a paper on the Clay and Gravel Soils of London and the Relative Advantages of Dwelling upon them. The paper was illustrated by a geological map of London and by diagrams of sections drawn through the Thames basin, showing that the soil nearest the river bed was invariably gravel, while the districts farther away were clay. Tables were also shown giving the height, elevation, soil, density of population, and death-rate of every sanitary area of London. These statistics, Dr. Clippingdale contended, proved that living on clay was not so injurious to health as was commonly supposed, and that as all the hills around London were of clay they resembled a clay table basin which, if turned upside down, became immediately drained of water poured upon it, whereas the greater mortality was clearly shown by the tables to be connected with the low-lying and level districts where the soil was generally gravel. Density of population and the class and occupation of the inhabitants were also acknowledged by Dr. Clippingdale as important factors in determining the death-rate, but these did not, in his opinion, fully account for the marked difference between the mortality upon clay hills and that upon gravel levels. The omission from the Registrar-General's returns of statistics with regard to rheumatism was regretted, as this disease was well known to be influenced by soil. In conclusion, Dr. Clippingdale pointed out that the important thing was to live upon a hill; if a hill could be found of gravel all the better, but there were no hills of gravel in or near London, and the statistics which he had brought forward proved, he contended, that the healthiest places near London were those on the clay hills surrounding it.—Dr. J. Groves (Carisbrooke) said that he concluded that Dr. Clippingdale did not intend that the conclusions drawn from the circumstances of London should be applied outside it. The experiences of a wider district in which various formations were at the surface would scarcely support such conclusions. In rheumatoid affections it was well known that the conditions ameliorated when the subjects of them removed from a clay soil to a gravel or other porous soil. His experience of London taught him that the overcrowded conditions which obtained in certain districts were responsible for high mortality rather than the nature of the soil, and the wonder was that the mortality was not greater.—Dr. A. P. Luff congratulated Dr. Clippingdale on the courage which he had shown in coming forward as a champion of clay soil, but he ventured to differ from the deductions which had been drawn from the figures given in the paper.—Dr. Harry Campbell drew attention to the fact that a well-drained gravel soil might be in some respects unhealthy—that anæmia was especially common in the neighbourhood of Aldershot. In comparing the healthiness of the gravel and clay districts of London it must not be forgotten how extraordinarily well drained London was as a whole, and the fact that wide areas were rendered impermeable to rain by being covered with houses and pavements. The low mortality of the clay eminences might be partly accounted for by the fact that they were sought after by the more wealthy residents who could command the best sanitary conditions. He did not, however, doubt that on the whole gravel was more healthy than clay.—Dr. R. Fortescue Fox held that a clear case had been made out for the salubrity of clay soils if well situated and well-drained.—Dr. W. Ewart was able to agree with almost all the views which had been expressed. Their apparent divergence was explained away by the fact that the generally accepted statement as to climate would not be applied to London which was exceptional, not only as a town, but also as a geographical and as a geological district. Its own clay area, besides being artificially protected by impermeable layers, was admirably drained by its water courses and by its sewers and was everywhere on the slope, and, moreover, was limited north and south by elevated ridges of a different formation. Clay regions had a damp and cold atmosphere because they usually consisted of extensive plateaux without natural drainage On the other hand, the London gravel, instead of being a highly aerated soil conducive to warmth and dryness of air, was in its lower strata soaking in water and therefore less healthy than it was generally supposed to be.—Dr. E. Solly (Harrogate) said that the healthiness of a soil could be discussed under two heads—the physical effects, i.e., coldness, humidity, &c., and the zymotic effects due to contamination with sewage. Further statistics were needed, but as regarded the latter point he would far sooner live in a house on a clay soil in a town, because sewage leakage tended to follow the course of the sewers instead of permeating the soil.—The experiences of Mr. G. H. Thompson (Buxton) coincided with those of Dr. Luff (excluding London), that chronic rheumatic diseases were more prevalent on clay soil than they were on other soils, and patients had frequently told him that they had derived benefit by removing from clay to non-clay districts. Intercurrent diseases might account for the non-appearance of chronic rheumatic diseases as a cause of death in the returns of the Registrar-General.—Other speakers followed and the discussion was closed by a few remarks from the President.

GLASGOW SOUTHERN MEDICAL SOCIETY.—A meeting of this society was held on Dec. 19th, 1901, Dr. John Stewart, the President, being in the chair.—The meeting, which was a special one, was called for the express purpose of considering what action, if any, should be taken regarding the relation of the General Medical Council to the medical profession In introducing the discussion the President said . The medical profession in this part of the country has been brought more closely into contact with the General Medical Council during the last 12 months than at any period of recorded time. The idea we fondly cherished of the General Medical Council that it was a body having the interests of the medical practitioners at heart anxious to listen to grievances has but proved a pleasant dream from which we have had a rude awakening. You are aware that the medical practitioners of Glasgow and the west of Scotland had occasion to approach the General Medical Council, and sent to London a deputation in support of a memorial. At the same time and on the same subject the Glasgow Southern Medical Society forwarded to the Council a petition signed by the office-bearers. It is now a matter of history that the memorial was not accepted; the deputation was not received, while the petition from our society was not even acknowledged. We are therefore forced to the conclusion that the General Medical Council as presently constituted is not in sympathy with our work as general practitioners. Further, our attention has been particularly drawn to the manner in which the General Medical Council discharges its judicial functions. The only general power it possesses is in connexion with a charge of infamous conduct in a professional respect, and in this capacity many have come to regard the Council with absolute distrust. We have seen it in the exercise of its functions frame an indictment the terms of which betrayed either complete ignorance of the law or a deliberate ignoring of the law. We have known it issue an indictment which made a grave charge of illegal conduct against the accused—viz., that of employing another to break the law—and we have seen it sustain the charge on facts which to the unbiased mind did not bear out the indictment, much less substantiate a charge of infamous conduct. We note that though in support of the charge of infamous conduct the Council furnishes particulars in an indictment to which it gives publicity, yet in considering the charge it ignores particulars and makes a test by facts which have little or no relation to the terms of the indictment. We believe, therefore, that the General Medical Council is not an impartial judge and that in questions which ought to be decided by legal methods it is influenced by sentiment and prejudice. Need we wonder, then, that many accused parties, though conscious of their innocence, should feel that for their own safety it is better to appear before the tribunal with "bated breath and whispering humbleness" and express regret. It is our duty, however, to protest strongly against the action of the Council in so humiliating men of staunch integrity and of holding up the profession in this part of the country to public ridicule and scorn. It is unanimously held that the General Medical Council is not a legislative body—that it has no power to make or alter laws; but a moment's consideration will show that the unrestricted power it possesses, of which it takes the fullest advantage, of defining what is infamous conduct makes it a very powerful legislative body indeed It has only to say, Do this or the Council will adjudge you guilty of infamous conduct; or Don't do that, or by the power committed to the Council under such and such sections of the Medical Acts the Council will erase your name from the Medical Register. Surely no body of men should possess such absolute power, certainly not any body whose judicial fair-mindedness is open to doubt. From these considerations, from the unsympathetic attitude of the Council to the medical profession, from the prejudiced administration of its judicial functions, from its arrogant assumption of legislative powers, from its apparent laxity in regard to its administrative duties and from other considerations—from sins of omission and from sins of commission—the medical profession has ceased to repose that confidence in the General Medical Council which as the governing body of medical education and registration it ought to command. Reform is needed and we believe that in the first place reformation should be in the direction of (1) a great increase in the number of direct representatives, and (2) a complete withdrawal of the penal powers of the Council, or at least a more restricted definition of the same. The present time, the President believed, was opportune to petition Parliament. It would not be difficult, he thought, to show that the profession ought to be more liberally represented on the Council, and many believed that it should be asked that the erasure from the Medical Register should be relegated to the courts of law. The President then invited discussion on the subject in which many took part, and at the close the following proposition was moved and adopted, viz. :—

> That the Council of the Glasgow Southern Medical Society be empowered to take steps to draw up a memorial for presentation to the Members of Parliament and to Parliament itself seeking support for an increase in the direct representation to, and restriction of the penal powers of, the General Medical Council, and that other medical societies be invited to cooperate.

Sheffield Medico-Chirurgical Society.—A meeting of this society was held on Dec. 19th, 1901, Dr. C. H. Willey, the President, being in the chair.—The following specimens were exhibited (*a*, microscopical; *b*, macroscopical):—Mr. R. Favell: (1) A series of Uterine Fibromyomata (*b*); (2) Diseases of Fallopian Tubes (*b*); and (3) a Parovarian Cyst (*b*).—Dr. T. H. Morton: (1) Blood Cysts from the Uterus (*b*); (2) Tubal Ectopic Gestation (*b*); (3) an Intestine Strangulated by a Band (*b*); and (4) an Intestine Strangulated by a Loop (*b*).—Mr. R. J. Pye-Smith: A Pylorus Excised for Malignant Disease (*a* and *b*).—Mr. E. J. Scorah: (1) Sarcoma of the Small Intestine (*a*); (2) Carcinoma of the Small Intestine (*a*); and (3) Cirrhotic Kidneys (*b*).—Mr. S. Snell: (1) Encapsuled Sarcoma of the Orbit (*a* and *b*); (2) Epithelioma of the Cornea (*b*); (3) Tubercle of the Iris (*a*); (4) Endothelioma of the Orbit (*a*); (5) Choroidal Sarcoma recurring in the Orbit—(i.) a section of the eyeball, (ii.) a growth from the orbit, (iii.) the bony walls of the orbit exfoliated after the application of chloride of zinc, and (iv.) microscopical sections of tumours; and (6) a collection (about 70) of Mounted Sections of Eyes.—Dr. G. Wilkinson: Hydatid of the Lower End of the Femur (*b*).—Dr. A. J. Hall: (1) Typhoid Ulcers (*b*); (2) Mucous Casts of the Intestine (*b*); (3) Brain—thrombotic softening (*b*); (4) Aortic Aneurysm (*b*); (5) Fatty Degeneration of the Heart (*a*); (6) Acute Yellow Atrophy of the Liver (*a*); (7) Fatty Degeneration of the Kidney (*a*); and (8) Amyloid Degeneration of the Heart (*a*).—Specimens illustrating various features of Tuberculosis were exhibited by Dr. J. Robertson, Dr C. M. Hector, and Dr. Hall, including Cultures of Bacillus Tuberculosis, Streptothrix, and Actinomyces; microscopical specimens of Tuberculosis of the Udder of the Cow, of the Lung of the Horse, of the Glands of the Guinea-pig, and of various Human Organs; Lupus Nodules, Urine, &c.; specimens illustrating Tuberculosis in Animals; and a large collection of specimens illustrating Tuberculosis of different Organs, both Human and Animal.

Nottingham Medico-Chirurgical Society.—A meeting of this society was held on Dec. 18th, 1901, Mr. E C. Kingdon, the President, being in the chair.—Dr. H. Handford read notes on a case of Right Hemiplegia from Thrombosis of the Cerebral Veins occurring in a young woman, aged 25 years, some three weeks after removal of double pyosalpinx; death occurred three days after first onset. At the necropsy a firm old grey adherent clot was found in the superior longitudinal sinus and hard black clots were found in the left cerebral veins. There were no clots in the arteries, hæmorrhage in the substance of the brain, or excess of fluid in the subarachnoid space. The facts of the walls of the superior longitudinal sinus being so fixed that alteration of its calibre did not occur as in other veins, that the veins took an ascending course, and that the blood-current in them was exceedingly slow all favoured the formation of clot in that position, and when in addition the cerebral veins were involved the condition was usually fatal.—The President, Dr. W. B. Ransom, and Dr. A. W. C. Peskett discussed the subject, and Dr. Handford replied.—Dr. A. Fulton read a short paper on the Treatment of Epidemic Diarrhœa in Infants. He advocated clearing out the contents of the alimentary tract, withholding all food for a time, then giving small feeds of white of egg beat up with an equal amount of water till convalescence. Minute doses of tincture of opium and acetate of lead were useful in certain cases, and as preventive treatment the sterilisation of milk during an epidemic.—Dr. W. B. Ransom read a paper entitled, "Should Milk be Boiled?" first pointing out how easily milk became a vehicle of disease; even when coming from a healthy cow it was frequently much contaminated by pollution from the milker's hands, by excreta from the byre in which the cow was milked, and by dust of all kinds which settled on the surface of exposed milk, which must occur during its transit and when left for hours in some possibly insanitary place before its final consumption. It had also been frequently shown that many zymotic diseases were traceable to the use of unboiled milk, that 10 minutes' boiling would destroy hurtful bacilli, that the nutritional value of boiled milk was equal to that of raw milk, and that its rate of digestion was practically the same. Dr. Ransom further advocated the municipal distribution of sterilised milk during epidemic diarrhœa.—The papers of Dr. Fulton and Dr. Ransom were discussed together, as running on similar lines, by the President, Dr. Handford, Dr. W. Hunter, Dr. Peskett, and Mr. R. G Hogarth.—Dr. Fulton and Dr. Ransom replied.

Windsor and District Medical Society.—The third meeting of the session of this society was held on Dec. 18th, 1901, Surgeon-General H. Cayley (retired) being in the chair.—Mr. J. W. Gooch showed a skiagram of a case of Injury to the Elbow-joint, occurring in a lad, aged 16 years. The internal condyle was seen to be broken off.—Dr. E. B. Hulbert showed (1) a specimen of Cancer of the Summit of the Bladder adherent to the Anterior Abdominal Wall from a man, aged 70 years (there were secondary deposits in the liver); and (2) a specimen of Extensive Cancer of the Ileo-cæcal Valve from a man, aged 78 years.—Captain F. S. Brereton, R.A.M.C., showed (1) a patient with a Large Swelling over the Manubrium Sterni which had improved greatly under anti-syphilitic treatment (there was a similar swelling on the tibia); and (2) a case of Morbus Cordis occurring in a young soldier. The disease was considered to be aortic.—Captain J. H. Power, R.A.M.C., showed a patient with Stiffness of the Arm and Shoulder-joint following an injury. There was some wasting of the muscles and there was a suspicion that the brachial plexus had been injured.—Mr. H. G. Plimmer delivered an address entitled "The Present State of the Cancer Question." The lecture commenced with a brief but concise history of the growth of the parasitic theory of cancer from the discussion at the Academy of Medicine at Lyons in 1773 to the recent work of Ruffer, Sanfelice, and others. The similarity of the conditions under which cancer occurred with those appertaining to various infective diseases was pointed out. Further, after a detailed description of the bodies so often found included within the cancer cells and a reference to the frequency with which they were found, the results obtained by cultivation of the organism and its introduction into the bodies of living animals were described. Besides the actual preparations which were shown under the microscope, lantern slides were thrown upon the screen, showing, first, the typical structure of carcinoma, and, secondly, the actual cell inclusions. Slides showing the organism obtained by cultivation were also shown, and, finally, endothelial growths from the lungs of a guinea-pig caused by the introduction of the organism into the animal's body. A single section of a cornea similarly treated exhibiting true epithelial proliferation was also shown.—Surgeon-General Cayley having proposed a vote of thanks to Mr. Plimmer for his very interesting and instructive address, it was seconded by Dr. G. H. Sealy, and being put to the meeting was carried unanimously.

# Reviews and Notices of Books.

*Atlas and Epitome of Special Pathologic Histology.* By Docent Dr HERMANN DÜRCK, Assistant in the Pathological Institute, Prosector to the Municipal Hospital, Munich. Vol. II. Authorised Translation from the German. Edited by LUDVIG HEKTOEN, M.D., Professor of Pathology, Rush Medical College, Chicago London and Philadelphia: W. B. Saunders and Co 1901. Crown 8vo. Pp. 198 With 122 Coloured Illustrations. Price 13s

THIS volume completes Dr. Dürck's Atlas of Special Pathologic Histology, the first volume of which we reviewed two years ago.[1] The work forms one of a series of medical hand atlases which are in course of publication on an international coöperative system. Arrangements have been made to publish these books in no fewer than 13 languages and by dividing the heavy cost of production among a number of publishers it has been possible to issue them at a comparatively low price. The success of the venture would seem to be assured, for the American publisher anticipates a sale of over 100,000 copies of the 14 volumes which have already appeared.

This volume contains 122 plates which illustrate in colours the morbid histology of diseases affecting the liver, pancreas, urinary organs, central nervous system, skeletal muscles, skin, bones, joints, and the male and female sexual organs A consideration of the diseases of the central nervous system and of those of the organs of special sense have been omitted as they are discussed in other atlases, while the subject of genuine neoplasms is reserved for a volume on General Pathological Histology. The illustrations, beautifully executed lithographs, maintain on the whole a high standard of excellence. The author tells us that in portraying the various morbid processes he has avoided the use of combination pictures—i.e, those compounded of several microscopic views—and that each plate represents as far as possible what may actually be seen under the microscope It is open to argument whether for beginners, for whom this book is intended, this is the best course to pursue. The description in the text is based on the appearance of several specimens and therefore often indicates more than can really be seen in the illustrations, and particularly is this apt to be the case here where the latter represent mainly examinations under a low power of the microscope The text, which is a condensed epitome of histology, has, we think, lost some of its value in the process of compression, for it makes stiff reading for anyone who is not familiar with the subject As a matter of fact, this atlas will appeal chiefly to those who wish to have by them a well-illustrated work with which to refresh their recollections of the histological changes produced by various diseases To such we can recommend it highly.

Diseases of the liver and kidneys have been studied in some detail, more than half of the book being devoted to these two chapters. The illustrations of amyloid liver exaggerate the indefiniteness characteristic of the affection unnecessarily, and the one on diffuse hypertrophic cirrhosis is not very instructive, otherwise the student will find the plates in this section excellent To the brain and spinal cord 22 plates have been allotted, to diseases of the skin 10, of the pancreas two, of the bones four, and of the joints two. The male sexual organs have six illustrations, while the uterus, ovaries, and tubes have the same number. These, we think, might have been omitted, as affections of the female sexual organs are treated of in a special atlas and the attention which they receive here is too slight to be of much profit to the reader.

While we cannot go so far as the American publisher and say that the book offers "a ready and satisfactory substitute for clinical observation," we have no doubt that those who are unable to continue their pathological studies practically will find this atlas extremely useful

*Die Malaria; Studien eines Zoologen. (Malaria; Studies by a Zoologist.)* Von BATTISTA GRASSI. Second and enlarged edition. Jena: Gustav Fischer. 1902. 4to, pp 250, with eight Plates and 15 Figures in the Text. Price 20 marks

GREAT advances have been made of recent years in our knowledge of malaria and Professor Grassi has played no small part in them The importance of the subject is made clear by the fact mentioned by the author in his preface that malaria prevails in two-thirds of Italy and that several millions of its inhabitants suffer yearly from it.

This book gives a most interesting account of the relationship of the malarial parasite to the mosquito (anopheles), but unfortunately it is marred by a keen discussion on the priority question. This becomes more regrettable when on p 35 an attempt is apparently made to minimise the researches of one of the pioneer workers in the subject. No further observation will be made here on this priority question as it turns the attention of the reader from the main object of Professor Grassi's excellent work.

After an historical survey of the malarial parasite in Chapter I. the author proceeds to give in Chapter II. an account of blood-sucking insects. He identifies with precision the various forms of anopheles which carry the malarial infections Many interesting questions are here discussed which have an important bearing on malaria, such as the habits of the anopheles and the distances to which they travel. In Chapter III. Professor Grassi describes the modes of catching and cultivating mosquitoes Chapter IV. is given up to anatomical considerations concerning anopheles, their eggs and larvæ, and anopheles claviger, pseudo-pictus, and superpictus receive a short description. The mode of life of these insects is discussed in Chapter V. In Chapter VI Professor Grassi gives an account of the experiments by which he arrived at the conclusion that malaria is transmitted by anopheles (and especially in Italy by anopheles claviger) and not by culex and other insects. He maintains that the parasite found in birds has nothing to do with the malarial parasite of man, and he quotes from the various authorities who uphold the same view The development of the malarial parasite in the body of the anopheles, including the arrival of the sporozoits in the salivary glands, is traced out in Chapter VII The author deals in a very suggestive manner in Chapter VIII with the objections which have been raised against the relationship existing between the anopheles and the malarial infection He says that during many months of diligent search he has never discovered a single case of malaria in which anopheles bites could be absolutely excluded and he thinks that no other view of the transmission of malaria is tenable In Chapter IX, on Prophylaxis, Professor Grassi advocates the compulsory treatment of the malarial patient because this patient is a danger not only to himself but also to the rest of the community It is most important to recognise that malarial suspects should be made to include not only those who have recently had malaria but also those who have had the disease during the past two years, and even those who have resided in a malarious district during a similar period though they think that they have never had malaria This proposal may seem to many to be a very drastic one, but the eradication of the disease is what the author would aim at. The prophylactic treatment by quinine, &c., should begin in January and be continued until the end of June. Avoidance of the bites of anopheles must be carried out by means of curtains, nets, and gloves The author repeats that it is the duty of the

---

[1] THE LANCET, Dec. 30th 1899, p 1817.

State to make both prophylactic and actual treatment as far as possible compulsory. Under the heading of "Destruction of the Anopheles" Professor Grassi points out that anopheles claviger winters in houses, and that every female destroyed during this time is worth thousands killed during the malarial months. Destruction of the larvæ in the water has been attempted by means of chemical substances and sometimes with success. The author thinks, however, that this is a more difficult matter than it appears to be. He maintains that by means of suitable treatment of the individual and by protecting him against the bites of anopheles more will be done towards eradicating the disease than can be effected by sanitary measures connected with the soil ("Boden assanierungen"), although these latter must not be neglected. In Chapter X. Professor Grassi relates an experiment in prophylaxis carried out in 1900 on the very malarious plain of Cappacio; 10 houses were included in the experiment, and of 112 persons concerned in it only five cases of malaria were noted and these only lasted a short time. In an appendix the author speaks of esanopheles, a remedy containing quinine, arsenic, and iron, as a valuable agent in the prophylactic and actual treatment of the disease. The plates appended form a valuable addition to the work.

This book by Professor Grassi is an important contribution to the subject of malaria and it presents certain advantages in having been written by a distinguished zoologist.

---

*A Manual of Determinative Bacteriology.* By F. D. CHESTER, Bacteriologist of the Delaware College, Agricultural Experiment Station, and Director of the Laboratory of the State Board of Health of Delaware. London: Macmillan and Co. 1901. Pp. 401. Price 10*s.* 6*d.*

IT is very difficult quite justly to appreciate the value of this book. Of necessity such a work cannot be final, nor can it be more than partially successful, and that not from any failure on the part of the author, but because our knowledge of most micro-organisms is so incomplete or misleading that it is often impossible even to recognise a microbe from its description, still less to classify it. All bacteriologists must, however, be grateful to Mr. Chester for placing at their disposal the immense amount of information which this book contains in an easily accessible form and for the great labour involved in its production. The author takes a perfectly clear view of the value of the material with which he has had to deal, and, as he says, "the conclusion is permanent that probably nine-tenths of the forms of bacteria at present described might as well be forgotten or given a respectful burial." Most bacteriologists would echo this sentiment. In his modest preface the author claims only that he has made the best of such material as was available and trusts that the tables will serve for identification if not for classification. For this reason he chooses the term "determinative" rather than "systematic" to describe the manual.

One great merit of this book is that it has a perfectly definite aim and that the whole work is subsidiary to the central idea. It is further an honest attempt to systematise our knowledge of the micro-organisms already described and is a piece of work which had to be done before further advances in this direction could be made; it clears the jungle of duplicate names and synonyms. But it does more than this, as it lays down definitely the lines on which future descriptions of micro-organisms must be based. It insists on the necessity of cultures on standard media and upon the importance of the bio-chemical reactions of micro-organisms in the determination of species. It systematises the descriptive terminology to be used, so as to avoid the picturesque but hazy language at present employed in describing cultures, and illustrates by diagrammatic woodcuts the types of cultures and colonies to which the suggested terms are applied. The great difficulty in using old descriptions for systematic purposes lies in the fact that the cultures of organisms were not made under standard conditions, so that an organism such as the bacillus zopfii (p. 248) appears in this book as not liquefying gelatin, while Frankland describes it as a liquefying organism. When such a broad difference as this fails—and it fails constantly—it can hardly be expected that smaller differences should be trustworthy. But while recognising that standard media of standard reaction are absolutely necessary for systematic work and willingly acknowledging that advance can only be on these lines, yet it is doubtful whether we shall advance by persuading ourselves that we have attained either a standard medium or a standard reaction. In England each laboratory is still a law unto itself so far as media and reactions are concerned. In America the Laboratory Committee of the American Public Health Association has issued instructions for the manufacture of media and for their titration, but though greater uniformity is thus secured it is far from being absolute. At present it is impossible to discard media containing complex organic compounds of uncertain or readily changed composition and to use only bodies of known composition easily obtained in a pure form. Unfortunately, also, it is not possible to do more than to standardise approximately the reaction of complex organic mixtures like our media. When a standard has been fixed we have to depart from it in order that certain microbes may grow; many earth organisms would not grow, it was found by the author, on media of standard *titre*, and hence all descriptions must be accompained by a statement of the *titre* employed. Again, we meet with the difficulty that the morphological and chemical characters of an organism change by sub-culture on artificial media, and though, as the author says, after a series of sub-cultures the organisms settle down and "establish characters which are reasonably constant," yet the characters which have been lost are just as important, and generally more distinctive, than those which are retained. It is convenient, and perhaps necessary for systematic classification, that we should wait until "reasonably constant characters" are attained, but this waiting will not facilitate recognition of micro-organisms when first isolated. All will agree with the author's dictum that "to publish a description of a bacterium after the study of one or two generations is the height of superficiality." The basis of classification adopted is, as usual, a morphological one, with the sub-groups distinguished, so far as possible, by bio-chemical reactions, but how difficult this grouping is may be seen when we find the bacillus typhosus separated from others of its sub-group by the character of "not producing pyogenic reaction by inoculation into experimental animals." This is not in accord with Sanarelli's results. The bacillus enteritidis (Gaertner) is also said to coagulate milk and to ferment lactose, characters which it is not generally supposed to possess. But though it would be easy to criticise the classification, yet the book contains so much positive good that it would be ungrateful to find fault, especially as the weaknesses are due to the inherent nature of the subject and could not, probably, in the present state of our knowledge be avoided

---

*The Hampstead Annual, 1901.* Published yearly by SIDNEY C. MAYLE, High-street, Hampstead. Price 2*s.* 6*d.*

WE have received the copy for the year which has just passed away of this interesting annual, and are glad to read that the literary contents and illustrations keep up to the high level of those which have appeared in previous issues. The place of honour in the "Hampstead Annual" is given to a brief biographical sketch of Sir Walter Besant written by Dr. Squire Sprigge, in which the dead writer's unbounded zeal on behalf of, and generosity to, his fellow-craftsmen are well brought out. The most interesting article is one entitled Londoners and London, by Sir Richard Temple, in which the famous financier and Indian official points out how little the inhabitants of the metropolis know of their inheritance, how blind they are to the beauties and splendours of our great city and its environment. Other well-informed articles include one on Sir Francis Palgrave as a Precursor of Ruskin, by Dr. Richard Garnett, and one on George Romney, for years a denizen of Hampstead, by Miss Beatrice Marshall; while to "The Hampstead Notebook" Sir Samuel Wilks contributes some notes on Keats as a medical student. We should be glad to see other suburban centres, especially those that have a historical past, initiate an annual on the lines of the "Hampstead Annual." We think that such periodicals would tend to some degree to dispel the dense ignorance of the Londoner concerning the London to which Sir Richard Temple calls attention. Such places as Chiswick, Fulham and Hammersmith, Chelsea, Stoke Newington, Canonbury and Highgate, to mention only the first names that occur to us, have a history rich in traditions and full of literary, artistic, and other points of interest which is well worthy of preservation Local celebrities and the local associations of national celebrities are in danger of being forgotten owing to the fact that London, as a whole, is not merely the capital of England, but the capital of the empire, so that such publications as the "Hampstead Annual" serve an admirable purpose, and also provide good reading.

---

## LIBRARY TABLE.

*The Guide to South Africa.* Edited by Mr. A. SAMLER BROWN and Mr. G. GORDON BROWN. Ninth (1901–1902) edition. London: Sampson Low, Marston, and Co., Limited Pp. 475 Price 2*s.* 6*d.*—This is the ninth edition of this well-known guide which is now produced annually by the Union-Castle Mail Steamship Company for the use of tourists, sportsmen, invalids, settlers, and all classes, in short, whose business may take them to our enormous possessions in South Africa. The book is clearly written and neatly illustrated with coloured maps, plans, and diagrams, while a full and carefully prepared index and table of contents ensure the reader being able to ascertain what he is looking for with the maximum of speed and minimum of trouble. How many books of reference suffer terribly in their utility by their failure to indicate what may be found within their covers or where to find it? Everyone whose lot it is to work as a journalist has felt the waste of time that such incomplete guides to knowledge cause, and will recognise that when we say that the "Guide to South Africa" has no such drawbacks we are giving it praise that is well earned. The section on South Africa as a Health Resort is not very long and does not enter into much pathological or therapeutical detail. It is sought by means of the diagrams and maps to depict the climatic zones in such a way as to enable those ignorant of South African geography readily to distinguish the places most suitable for certain physical conditions, and medical men who are consulted as to the advisability of a patient proceeding to this or that locality should find the information of service, as considerable pains appear to have been taken to make it trustworthy. But we are glad to note that in more than one place explicit caution is given against the shipping of serious invalids indiscriminately to Cape Town or Durban. Certainly South Africa, to speak generally, is not at the present time an ideal country for a sick man; while no particular patient should proceed there without medical advice as to the propriety of his doing so, and some accurate knowledge of the conditions of life that he may expect on arrival.

*Medical Monograph Series, No. 5: Menstruation and its Disorders* By A. E GILES, M D., F.R.C.S. Eng., M.R C.P. Lond. London: Baillière, Tindall, and Cox. 1901. Pp 100 Price 2*s.* 6*d* net.—In this number of the Medical Monograph Series Dr. A. E. Giles has written an excellent account of menstruation and its disorders. The book is divided into two parts, the first treating of the Physiology of Menstruation and the second of its Disorders. The views published by Walter Heape upon the changes in the uterus and the relationship of "heat" or "œstrus" to menstruation are followed by the author and clearly explained. This theory of the exact meaning of menstruation in the human subject is the most satisfactory and convincing that has yet appeared and we quite agree with Dr. Giles in thinking that it probably represents the true relationship of this process. A good many of Dr Giles's own observations are included in the book, such as the instructive table on page 58—a table to show the relation between the age of puberty and sterility. The conclusions arrived at are that if menstruation begins between the seventeenth and eighteenth year the woman is very likely to have children; if it begins between 18 and 19 years of age the degree of relative infertility increases; and if at or after 20 years of age the rate of sterility is high. The author does not mention steaming the uterus under the treatment of uterine fibrosis, a condition for which we think it especially indicated The book is pleasantly written, contains a good deal of information upon an important condition, and is worth reading.

*The Human Figure in Motion: an Electro-photographic Investigation of Consecutive Phases of Muscular Actions.* By EADWEARD MUYBRIDGE Commenced 1872, completed 1885. London: Chapman and Hall, Limited. 1901. Pp. 280. Price 20*s.* net.—The veteran Mr. Muybridge, who was the pioneer in the photography of rapidly moving objects, has produced a most interesting book. In all there are 384 separate figures, both of men and of women, walking, running, jumping, dancing, and performing various motions. Everyone will remember Mr. Muybridge's instantaneous photographs of running horses and the extraordinary and ungainly positions into which these animals got for fractions of a second The human being, perhaps from only using two limbs for purposes of locomotion, does not look so awkward as does the horse, but the photographs show very well how different is the real motion from the apparent motion. Take the figures of athletes running, for instance (pp. 35 and 37), and note how, in reality, during a great part of the cycle the feet are both off the ground at once. Besides men, there are figures of women and children and the whole work will be found of great use, not only to artists, but to all who wish to study movement in the human subject. Although the figures are in general reduced in size from those published in the eleven-volume edition, yet they are in most cases perfectly clear and the selection is on the whole, we think, a good one We rather wish that the series entitled, "Getting out of Bed," had been retained, for it shows admirably how silly are the common phrases, "He sprang out of bed," or "He jumped out of bed" These two acts are impossible.

*Wonders in Monsterland.* By E. D. CUMING. Illustrations by J A SHEPHERD London: George Allen. 1901 Pp. 258 Price 6*s* —"Wonders in Monsterland" is a brave attempt to make children understand paleontology or, at any rate, to make them acquainted with some of the more obvious phenomena of the science. The book is profusely illustrated by Mr. J. A. Shepherd, with whose illustrations in the *Strand Magazine* in particular many of our readers may be familiar. The illustrations are capital, but we can hardly give quite such unqualified praise to the letter-press The fun is rather forced and the punning names are not very happy. Yet there is no doubt that any children reading the book would be familiarised with the appearance of the dinosaurus, the megatherium, the odontopteryx, &c. We can imagine that the reading of the book aloud to children, with an accompaniment of explanation, would form a good introduction to a visit to the Natural History Museum, South Kensington; but we doubt whether the book is one that children would be likely to read for themselves or to get very much interested in unless they could see the bones, fossils, or other presentments of the monsters whose doings are detailed.

*"Ugly": a Hospital Dog. Recitations and Readings.* By GEORGE H. R. DABBS, M.D. Aberd. London: Charles William Deacon and Co. 1901. Pp. 200. Price 1*s*.—Dr. Dabbs has written an unpretentious little book which is divided into two portions. The first is a collection of hospital stories supposed to be related by a bull-dog. They deal with incidents connected with hospital life, and there is no reason why most of them should not have happened, but the non-professional reader will not, we hope, think that every hospital is such a home of romance as "Ugly" makes out. However, the stories make good reading, and no doubt the "Recitations and Readings" will come in usefully at the holiday party. We may add that any profits accruing from the sale of the work will be devoted to King's College Hospital.

*An Idler's Calendar.* By G. L. APPERSON. London: George Allen. 1901. Pp. 213. Price 3*s.* 6*d.*—Mr. Apperson's book is well named. He is indeed an idler, one who knows and appreciates at their proper value the delights of idleness. Real idleness, we may remark, consists not in doing nothing but in having nothing to do. Mr. Apperson's pleasant little essays conduct us through a lotus land of folk-lore and books, country smells and sights, like to the inimitable Thalysia of Theocritus and for a hard-worked practitioner we can cordially recommend Mr. Apperson's pages. We in London, at any rate, are forgetting how to be idle, and a great part of present-day illness is due to the fact that most of us never rest.

---

## JOURNALS AND MAGAZINES.

*The Journal of Experimental Medicine.* Edited by WILLIAM H. WELCH, M.D. Baltimore, U.S.A.: N. Murray. Vol. VI., No. 1, issued Nov. 29th, 1901.—The November number of the *Journal of Experimental Medicine* contains a series of interesting articles. The first of these is Dr. Theobald Smith's note on the Production of Sarcosporidiosis in the Mouse by Feeding with Infected Muscular Tissue, from which we gather that sarcocystis muris containing ripe mobile sporozoites is infective to grey and white mice, and that the muscle fibres of these animals are invaded by the parasites, which are readily recognisable after the forty-fifth day, the parasite at this stage as a rule being many times larger than the sporozoite which it presumably represents. He also states that "within two and a half to three months the parasite has reached the final stage in which it consists of a chambered cyst filled with sporozoites mobile at the temperature of the body and capable of infecting other mice." A study of Chronic Hyperplastic Tuberculosis of the Intestine, with report of a case, is contributed by Dr. August Jerome Lartigan, who concludes that the treatment of the condition is obviously surgical, extirpation of the diseased tissue promising good results in a fair proportion of cases, whilst, as he points out, Nové-Josserand reports a recovery following simple laparotomy. Dr. W. G. MacCallum describes a case of multiple myeloma in which the new growths appeared to extend from the bone-marrow and show very gradual transitions into it. The cells of this tumour differ from the bone-marrow cells only in so far that they lack the specific granules of the myelocytes; they also differ considerably from plasma cells in essential particulars. They appear to be directly related to the myelocytes and are probably derived from the large non-granular forerunners of these cells. They undergo degeneration, they contain cell-inclusions, and red blood corpuscles are numerous in parts of the tumour. Dr. MacCallum also contributes with Mr. S. S. Buckley a description of an epizootic in horses known as "acute epizootic leuco-encephalitis," a condition found among horses in Maryland, resulting in the death of a great many animals after a very brief illness. It is a kind of cerebro-spinal meningitis, in which, however, the investigators were able to find no organism which they were justified in looking upon as being the etiological factor in this disease. Dr. William Sydney Thayer has an interesting article on the occurrence of strongyloides intestinalis in the United States. This parasite was described by Normand in 1876 and carefully studied by Bavay in the same year as anguillula stercoralis. It was first discovered in Cochin China and is evidently found in the United States associated with a special form of diarrhœa, and in Maryland and Virginia it is probably more frequent than has been supposed. In temperate climates the development of the sexual free-living generation is apparently unlike that found in warmer climates, as here the direct transformation of the rhabditiform embryos into filariform larvæ predominates. Dr. Thayer considers that more systematic examination of the fæces, both in public clinics and in private practice, is much to be desired. An excellent bibliography is appended to this article.

*The Veterinary Journal.* Edited by Principal W. OWEN WILLIAMS, F.R.C.V.S., F.R.S. Edin. London: Baillière, Tindall, and Cox. December, 1901.—On opening the December number of the *Veterinary Journal* and reading the first two or three pages it is evident that veterinary politicians may be as lively as their medical brethren. The editorial article is refreshing in its outspokenness and patriotism—both professional and national. It is announced that the Carnegie Trust for the universities of Scotland will pay the fees of veterinary students who have the following qualifications: (1) They must be over 16 years of age; (2) they must be of Scottish birth or extraction, or must have given two years' attendance after the age of 14 at a school or institution under inspection of the Scotch Education Department; and (3) they must be qualified by preliminary examinations under the ordinances of the Scottish Universities Commission and the regulations of the Joint Board of Examiners to attend the classes for which payment of fees has been claimed. Dr. D. C. Chalmers Watson in an article on Cerebral Thrombosis in the Horse: a Clinical Study, pleads for a thorough investigation and a careful record of acute and chronic diseases in the horse and other animals. He thinks that material additions might thus be made to our knowledge of similar diseases in the human subject. A note on Veterinary Education in Holland as compared with similar education in this country is of some interest and shows that our veterinary students at any rate are not overdone with scientific work as compared with their colleagues in Holland. Mr. Henry Taylor of the New Veterinary College, Edinburgh, records Supernumerary Digits in the two fore-limbs of a Clydesdale foal. Professor Sheridan Delépine's article on the Communicability of Human Tuberculosis to Cattle, and Professor E. M. Crookshank's Introductory Address to the Royal Veterinary College are here concluded. Mr. C. Cummins Cherry, G.M.V.C., contributes a series of Reminiscences of the South African Campaign. There is also reprinted from the United States Department of Agriculture's Sixteenth Annual Report of the Bureau of Animal Industry for the year 1899, "The Nature, Cause, and Economic Importance of Ovine Caseous Lymphadenitis." This, as the editor points out, appears to be what is known to Scottish sheep-farmers as "cruels," a condition somewhat common amongst well-bred sheep. An abstract of the report on an experimental investigation of the methods of inoculation against rinderpest from the Bacteriological Laboratory, Muktesar, India, is interesting in so far that it gives a very careful *résumé* of the advantages and disadvantages connected with each method of inoculating against rinderpest that has, up to the present, been recommended. From this report it may be gathered that all those methods of protection in which the actual disease is produced in a modified form are of greater value than are those in which no disease is set up, the immunity in the former cases invariably being more lasting than in the latter. An account of the Vaccine Institute at Aldershot and of Uhlenhuth's biological test as an aid in the inspection of meat are both papers that will interest the general reader. A note on Colonel George Fleming, F.R.C.V.S., and the veterinary profession is continued in this number.

*The Quarterly Review.*—The issue for October, 1901, contains a long and scholarly article upon the Plague. This somewhat mysterious malady, the origin of which is lost in obscurity, has for ages exerted an influence over humanity greater than that of any other disease. Its fatality, its rapid spread, and the distressing circumstances attending infection with, or death from, it have combined to make it a most dreaded complaint. The reviewer states that the first actual records show that a fatal disease producing pestilential buboes prevailed in Egypt, Libya, and Syria in about the third century B.C. Another terrible epidemic prevailed in the reign of Justinian, and Bede records a great pestilence as prevailing in the seventh century A.D. which may or may not have been true plague. In the fourteenth century plague appeared in an unmistakeable form in a series of epidemics, now known as "The Black Death." In these islands the epidemics appeared in 1348–1349, in 1361, and in 1368. Sicily was infected before 1347 and practically no part of Europe escaped in one or other of the epidemics. During the three following centuries plague was never absent from some part of Europe, but from 1647 to 1664 London was virtually free from plague. In the spring of 1665, however, the Great Plague of London began. Western Europe was practically free during the eighteenth century with the exception of the Marseilles outbreak in 1720, but the disease continued from time to time in Eastern Europe. Constantinople was not free until 1841. By the middle of the nineteenth century plague was believed to be no longer a source of danger to Europe, although certain authorities had their doubts, and subsequent events proved that they were right. In 1879 an epidemic of plague appeared in Vethanka, a little village on the Volga, the disease having travelled up the Caspian from Resht to Astrakhan. Since then plague has become *pandemic*, for after 1894 the disease has appeared in nearly every part of the world, Glasgow, Cardiff, and London being infected in these islands. After giving a short *résumé* of the various outbreaks of plague which have occurred during recent years the reviewer passes to consider the questions of treatment and preventive measures. The former is extremely unsatisfactory. Yersin and Lustig have respectively prepared a serum, but the curative results are very inconsistent, although the sera confer a certain degree of immunity. Haffkine's serum, however, is noted as conferring an immunity which, although not perfect, greatly lessens the chance of a patient catching the plague, while if he should have it the attack is but a slight one. As to prevention, the system of quarantine is no longer in use, but its place has been taken by the modern system authorised by the International Sanitary Conferences of Venice, 1892, and of Dresden, 1893, which relies upon medical inspection of both ships and persons coming from an infected port. As a rule this system works well, although infection slipped through at Glasgow. The reviewer lays stress on the point that reliance is to be placed upon maintaining such conditions of national health that the germ may be extinguished as soon as it enters. Destructive epidemics of plague do not occur except in the midst of filth, overcrowding, and poverty. In India, however, in the words of the Indian Plague Commissioners, 1899—words gravely endorsed by the reviewer—"the fact must be faced that there are no means of stamping out the present epidemic of plague in India; that even with the best measures most rigidly applied a certain amount of danger subsists, and all that can be done is to lessen the danger as much as possible." As a contribution to the knowledge of a matter of unending interest the article deserves the attention of sanitarians and medical men.

# Analytical Records

FROM

# THE LANCET LABORATORY.

### (1) LIQUID PETROLATUM; (2) SOLUTION IRON PEPTONATE AND MANGANESE WITH ARSENIC; (3) TERPIN HYDRATE AND HEROIN TABLETS, AND (4) FUNCTIONAL TONIC TABLETS.

(*PARKE, DAVIS, AND CO., 111, QUEEN VICTORIA-STREET, LONDON, E.C.*)

LIQUID petrolatum is a perfectly clear, colourless oil, with neutral reaction and taste. According to our examination its specific gravity is 0·863, while it shows signs of boiling at 200° C., the boiling being brisk when the temperature reaches 250° C. The oil is of admirable purity and well adapted for administration. It is an excellent emollient for inflammatory conditions of the throat, for which purpose it is best inhaled in the form of a fine spray produced by a specially designed atomiser. The solution of iron peptonate and manganese with arsenic is a clear dark-brown fluid with sweet vanilla-like taste. It contains 0·6 per cent. of iron and 0·1 per cent. of manganese, with one-fiftieth of a grain of arsenic in each fluid drachm. The solution has no disagreeable effects on the digestive functions. It is, of course, a powerful tonic preparation, presenting its ingredients in an easily assimilable form. The following formula is an obviously useful one: terpin hydrate, two grains; and heroin, one-fiftieth of a grain, in chocolate-coated tablets. Chocolate-coated tablets are also prepared in accordance with the following prescription: powdered ipecacuanha, one-tenth of a grain; powdered black pepper, one grain; aloin, one-sixteenth of a grain; extract of nux vomica, one-quarter of a grain; and extract of gentian, one grain. This is a very good formula exercising a beneficial action on the functions of the digestive tract.

### PETANELLE FOOT POWDER

(PATÉ BURKE AND CO., 6, WOOL EXCHANGE, BASINGHALL-STREET, LONDON, E.C.)

Petanelle consists of peat fibre, soft and yielding to the touch, which possesses absorbent and deodorising properties. It affords an excellent vehicle for the absorption of liquid antiseptics. In the case of the petanelle foot powder the fibre has been moistened with formaldehyde solution. It gives off the peculiarly irritating smell of formaldehyde. This combination is said to have been very useful to soldiers, pedestrians, athletes, and others for keeping the feet in a healthy condition. It is of service in bromidrosis.

### OLD TAWNY PORT.

(JOEL DAVIS, 61, MARK LANE, LONDON, E.C.)

This port presents the characteristics of a wine that has been stored and matured in wood for many years. It is of a brown sherry colour and has the excellent bouquet and taste of matured port made from the famous grapes of the Douro district. It is very smooth and mellow on the palate and fruity. Analysis gave the following results: alcohol—by weight 18·23 per cent., by volume 22·36 per cent., equal to proof spirit 39·13 per cent.; extractives, 6·02 per cent.; sugar, 4·40 per cent.; mineral matter, 0·22 per cent.; volatile acidity reckoned as acetic acid, 0·072 per cent.; and fixed acidity reckoned as tartaric acid, 0·225 per cent. The wine is evidently an old genuine port matured in wood. It is therefore wholesome and, as the above analysis shows, is free from saccharine excess.

### ZOECO.

(Zoeco, Limited, Moorgate-court, London, E.C.)

This is a preparation of cocoa with the proteids of milk and sugar. It has the appearance of cocoa paste. It is very sweet to the taste and it is flavoured strongly but agreeably with cocoa. It is said that the proteids used have never been coagulated. It may be presumed, therefore, that concentrated milk has been employed. The following analysis which we have made is in favour of this deduction: moisture, 27·30 per cent. ; mineral matter, 3·08 per cent. ; sugar, 52·61 per cent. ; fat, 6·33 per cent. ; and proteids, 10·68 per cent. The preparation is no doubt a useful food and is of a pleasant character. Exception, however, might be taken to its use in some cases on account of the very large proportion of sugar which is present.

### ST. BONIFACE SPRING WATER.

(Agents: Ingram and Royle, East Paul's Wharf, 26, Upper Thames-street, London, E.C.)

According to our analysis St. Boniface water is saline, lithiated, and alkaline. It is derived from the St. Boniface spring, Bad Salz-Schlirf, near Frankfort-on-the-Maine, and has some reputation as affording relief in gouty affections. Our analysis showed it to contain 15·99 grammes of mineral salts per litre, of which 12·51 grammes were common salt, the balance being made up of chloride of magnesium, sulphate of calcium, and carbonate of calcium. It has a degree of alkalinity equal to nearly one gramme per litre of carbonate of soda. The amount of lithium salt is small, not more than one and a half grains per pint. The water contains rather less than its own volume of free carbonic acid gas. The presence of salines and alkaline salts with distinct traces of lithia would place it amongst the waters which have been known to relieve gouty and rheumatic conditions, although mere chemical composition would not always account for that effect, many waters said to be useful in gouty conditions containing nothing but a few grains of lime salts.

### (1) PEPTONE CORNELIS; and (2) PASTILLES COCAINE BRUNEAU.

(C. Richter and Co., 90, Great Russell-street, London, W.C.)

Peptone cornelis consists of small sponge-like fragments possessing a slight beef-like saline taste which is quite free from bitterness. The preparation is hygroscopic and is preserved in bottles the stoppers of which contain quick lime as a desiccant. It dissolves in water, giving a slightly opalescent solution and depositing phosphatic flakes. On analysis the following results were obtained: moisture, 3·05 per cent. ; mineral matter, 8·41 per cent. ; and peptone, 88·54 per cent. The mineral matter consisted of phosphates, a notable amount of iron, and some common salt. The preparation is of course a powerful nutritive and it has the advantage of being free from that unpleasant bitter taste characteristic of commercial peptone. The peptone was free from albumose, as was shown by the fact that its solution gave no precipitate with saturated solution of sulphate of zinc. The cocaine pastilles are designed for sedative purposes in the treatment of the throat and glands. Each contains two milligrammes of cocaine hydrochlorate and 0·05 gramme of borax, with one drop of tincture of aconite.

### VARIOUS SOAPS.

(Edward Cook and Co., East London Soap Works, Bow, London, E.)

With the exception of the "cambath" skin soap, which contains camphor, not one of these soaps submitted for examination gave any indication of the presence of alkali in excess, and this exception, after all, is only apparent, since "cambath" soap contains a comparatively large proportion of moisture, so that an alkaline reaction would be shown as the result of hydrolysis. Amongst the soaps received were "buttermilk" soap, "wild violets" soap, "tourists' shaving" soap, and "creamy shaving"-stick. The soaps one and all were free from irritants and furnished evidence of being made from materials of desirable purity. The "cambath" skin soap is very agreeable in the bath.

### KATHREINER'S PATENT MALT COFFEE.

(Agent: P. F. Voelter, 9, Blenheim-place, Leeds.)

It is difficult to tell as regards appearance the difference between the infusion of this malt coffee and that of ordinary coffee. Nor is its aromatic flavour much less pleasing. It really makes an excellent black coffee with strong stimulating properties and empyreumatic smell. It must be confessed, however, that it lacks a something which in our experience only true coffee can supply. It yields a rich, black liquor containing all the phosphates of the barley, and the refreshing effect of phosphates is well known. Of course, there is no alkaloid present. This malt coffee is evidently prepared with the greatest care, being very uniformly roasted. We made careful examination for arsenic, since, as is well known, that poison may be derived from the fuel used in the malting process. No response, however, was given to the most delicate test. We regard this as the best coffee substitute that we have so far examined.

### FIBROUS BEEF-TEA.

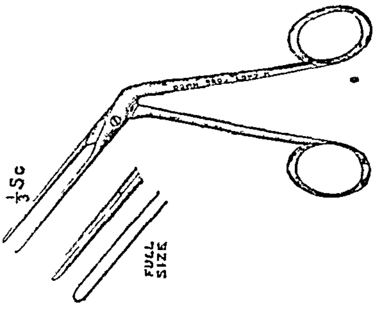
(Brand and Co., Limited, Mayfair Works, South Lambeth-road, Vauxhall, London, S.W.)

On opening the tin there proved to be a jelly inside containing a definite proportion of sediment in which under the microscope muscular fibre was detected as well as muscle albumin. This beef-tea, therefore, is something more than a stimulant—it has a decided nutrient value also. It has a pleasant, beef-like flavour. The preparation has been designed for hospital use, and tins containing 3 lb. costing 2*s.* 6*d.* are said to be sufficient to make 10 pints of beef-tea. In this form the beef-tea is certainly useful and convenient for hospital and invalid purposes in general.

## New Inventions.

### NEW PATTERN OF NASAL AND AURAL WOOL-CARRYING FORCEPS.

Most of the wool-carrying forceps for nasal and aural work are made to open horizontally, require a certain amount of pressure to close, and have enlarged and serrated ends. All these disadvantages are absent in the pattern here shown, the blades of which are smooth and slightly tapering (these when closed can be used as a probe), open vertically, and require no pressure to hold the wool securely; when used the wool can be easily dropped off, there being no irregularities for the fibres to cling to. If the wool is twisted round the blades it can easily be pulled off by means of a dental wool casket. They are very convenient for packing cavities. These forceps are made either with or without a take-off joint. They were made for me by Messrs. Down Bros., St. Thomas's-street, London.



A. Stanley Green, M.B., B.S. Lond.
Lincoln.

---

University of Cambridge.—The following were admitted to the degree of Doctor of Medicine on Dec. 12th: Evan Laming Evans, M.A., M.B., B.C., Trinity College, and James Graham Forbes, B.A., M.B., B.C., D.P.H., Christ's College.

# THE LANCET.

*LONDON SATURDAY, JANUARY 4 1902*

## The King's Sanatorium.

THE new year opens auspiciously for medicine The most important medical event of the year 1901 was the British Congress on Tuberculosis, and one of the things definitely decided by that Congress was the value of the part played by sanatoriums in the treatment of tuberculosis We take particular pleasure in announcing a remarkable endorsement of this view HIS MAJESTY THE KING has graciously consented to direct that a large sum of money, placed at his disposal for charitable or utilitarian purposes, shall be devoted to the erection in England of a sanatorium for tuberculous patients In allocating the fund entrusted to his discretion to such a purpose HIS MAJESTY is giving another example of the practical sympathy which he has with the needs of the suffering poor Not since EDWARD VI, himself a victim to tuberculosis, made himself responsible for the charitable foundations of Bridewell, Greyfriars, and St Thomas's Hospital, has any ruler of England shown such a deep and practical desire to benefit the necessitous sick as that manifested by the founder of the Prince of Wales's (now King Edward's) Hospital Fund for London As PRINCE of WALES the KING was well known to all his subjects as a warm hearted man—one whose dignity never prevented him from doing a kindness and one whose lofty position never blinded him to the troubles and trials of his subjects His succession to his inheritance has enormously increased his responsibilities, but it is clear that it has in no way blunted his sympathy with the most unfortunate section those who own his rule—the victims of disease

The KING has been guided in the matter by an Advisory ommittee, consisting of SIR WILLIAM BROADBENT, Bart, .C V O, SIR RICHARD DOUGLAS POWELL, Bart K C V O, r FRANCIS LAKING K C V O, SIR FELIX SEMON, Sir ERMANN WEBER, and Dr C THEODORE WILLIAMS, d the first step towards erecting the new sanatorium one that is calculated to insure useful results HIS AJESTY has been pleased to approve that the sum of £800 ill be awarded in prizes for the best essays upon sana riums for the victims of tuberculosis The essays, with l necessary constructive plans, are to be sent in to one of e honorary secretaries of the Advisory Committee by pril 15th 1902 the following conditions having to be served —

1 Medical men of all nationalities may compete The papers may be either the work of a medical man or the joint production of a medical man and an architect
2 The sanatorium is intended for 100 tuberculous patients—50 males and 50 females
3 Of the total number of beds 88 will be assigned to the more necessitous classes whilst 12 will be reserved for the well-to-do
4 The accommodation for all patients is to be comfortable a separate room being provided for each Superior arrangements to be made for the more wealthy patients
5 It may be taken for granted that the sanatorium will be erected on an elevated and sloping site with a sunny exposure and well sheltered from cold winds It will have a farm at a convenient distance and be surrounded by extensive grounds well wooded, and affording ample space for exercises of various kinds The soil will be dry and permeable and the water-supply abundant
6 The sanatorium must be fitted with the latest sanitary arrangements and equipped with all requirements for scientific research Provision should also be made for the recreation of the patients
7 Economy in construction will be an important consideration but it must not interfere with the reasonable comfort of the patients or the efficiency of the institution
8 The essays must be in English and type written
9 The essays must not bear the name or names of their authors but should have a motto and each essay should be accompanied by a sealed envelope bearing the motto on the outside and containing the full name and address of the author or authors inside
10 All essays and plans must be sent postage paid on or before the 15th April 1902 to one of the secretaries to the Advisory Committee
11 Three money prizes of £500 £200 and £100 respectively will be awarded in order of merit on the recommendation of the Advisory Committee for the three best essays provided they come up to the requisite standard of excellence Brevity will be an important consideration and a summary of the main features of the scheme should be appended to the paper Unsuccessful papers will be returned to the authors

The secretaries to the Advisory Committee are Dr P HORTON SMITH 15, Upper Brook street, London, W, and Dr J BROADBENT, 35, Seymour street, London, W

The eminently practical nature of these conditions will be obvious to our readers Just enough is told to the competing essayists to prevent them from going off the line while information that might hamper them is withheld from them They are not told, it will be observed, anything more of the actual site than that the sanatorium will be erected on an elevated, well sheltered spot with a sunny exposure, nor are they informed how much money is to be placed at the disposal of the architects, the sum being merely described as a large one That economy in construction will be an important consideration is not to prevent the sanatorium from being fitted with everything necessary to render the patients absolutely comfortable, while provision in the plans is to be made for the latest sanitary arrangements and for all the requirements of scientific research work The erection of a model sanatorium upon a design approved by so practical a body of physicians as the Advisory Committee should be an incalculable benefit to the community as well as to the patients It will give a stimulus to a movement already started, but not running as strongly as could be desired, for providing suitable sanatoriums for all tuberculous subjects to serve the needs of different districts of the country "If preventable why not prevented?" asked the KING 10 years ago, referring to the prophylaxis of certain common diseases in his inaugural address as President of the International Congress of Hygiene and Demography, and the manner in which he has decided to expend the charitable fund of which he has accepted trusteeship shows how he considers that his epigrammatic question should be answered as far as tuberculosis is concerned Tuberculosis must be prevented and no surer or wiser way of fighting this fierce and insidious foe to our national health could be devised than the foundation of a model sanatorium Such an institution will furnish county and municipal authorities all over the kingdom with an example to follow The circumstances of its erection will bring to their attention the advisability of attempting to provide similar assistance for the local needs of those in their sanitary charge; the model building will give them an opportunity of seeing what they should attempt actually to construct. To all medical men the KING'S decision to use a fund placed at his disposal "for charitable or utilitarian purposes" in erecting a model sanatorium for tuberculous patients will give particular pleasure. There is hardly a public institution in our country that cannot claim to exist to some extent "for charitable or utilitarian purposes." So that the choice left to HIS MAJESTY in the allocation of the money was immense. And he has been pleased to honour medicine by devoting the money to the foundation of a beneficent medical institution. In the name of the sick poor and in the name of the medical profession we thank him heartily, blending with our thanks a sincere hope that his coronation year may bring him many blessings.

◆

# The Consultant and the General Practitioner.

THE relationship of the general practitioner to the consulting surgeon or physician and *vice versâ* is very delicate. The subject is one which has frequently been discussed in our columns, the circumstances in which it appears on the *tapis* being both numerous and various. For THE LANCET is often asked by a correspondent for an opinion upon some particular case in which these questions of professional politeness and rectitude between medical men have arisen. Just as with the British Constitution, on the whole the most admirable socio-legal system existing, so with the medical profession the fact that natural indefinite growth has predominated above any formal declaration of doctrines and laws gives rise from time to time to questions for which no direct answer can be found in definite printed law, but the rights of which must be determined by adherence to those general principles on the understanding of which the medical profession has grown and substantiated itself.

At the very outset of discussing the mutual behaviour of the consultant and the general practitioner we may be confronted by the objection of one side that there is no such thing as a consultant. We can imagine him to say: "I am a surgeon pure and simple. Every surgical case of any kind is fish that comes to my net, but I attempt no other kind of work. Medical and gynæcological cases I refer to other people." Being prepared to do any surgical work that comes to his hand, whether the patient comes of his own initiative or because he has been recommended by a medical man, what is he to do in the former case? In the latter, when the patient brings a verbal or a written communication from a professional brother his course of conduct is, of course, plain enough. Common politeness alone would put him on the right path apart from any thought of professional etiquette—which, by-the-bye, is in many directions only a particular application of common politeness. He sees the patient and gives his opinion or not as seems fit in the particular circumstances, and in any case writes to the general practitioner about the case. So far matters are plain enough, and no difficulty can be easily imagined with regard to patient, practitioner, or consultant. Suppose, however, the first case, that in which a patient consults a surgeon or physician on his own initiative. Such an instance is the occasion of a letter which we publish in our correspondence columns from Mr. F. MONTAGUE MILLER. We do not think, judging from the bare facts, that our correspondent has grave cause for complaint against the particular consultant who saw his patient. To begin with, Is it the duty of the consultant to ask any questions as to how the patient comes to see him? We think it is. Many patients, either through ignorance or wilfully, will visit the consultant unknown to the practitioner. This can only become plain to the former if he habitually asks his patients, "Who is your usual medical attendant?" or some such question from which he can ascertain the position. Obviously if one member of the medical profession assumes a position in which he expects his opinion to be sought by other members of his profession it will be his duty as much as his interest to see that they are never the losers at his hands. Such a position naturally befalls hospital physicians and surgeons who gain an exceptionally wide experience in particular branches of work. Whether they accept the term "consultant" or not, their opinion and advice are likely to be sought by the general practitioner, and they should conduct their practice accordingly. Difficulty arises when, the question being put as we have suggested, the patient replies: "I do not want my usual medical adviser to know anything of this visit or its results." Such a case not uncommonly occurs. What is now the consulting surgeon's or physician's proper course? It must vary according to circumstances. Generally speaking, the right thing for him to do is to explain to the layman the propriety and the enormous advantage of admitting the general practitioner to a knowledge of what has been done. More particularly if an operation is advised will the consultant desire to have the presence of the general practitioner and his collaboration, for the after-treatment may be left mainly in his hands. Suppose, however, as occasionally happens, the patient says, "No; I am determined that Dr. —— shall have nothing to do with this matter." Some would say that the consultant must then refuse the case. This would be an easy solution of the difficulty, but unfortunately every case cannot be determined in this manner. The consulting surgeon or physician has a duty to the public as well as to his fellows. A member of the public has chosen to ask him, and him only, for his help. He is, we think, bound to give it unless in doing so he is absolutely breaking faith with his profession by constituting himself a sort of judge of, or even spy upon, a professional colleague. In short, no hard and fast line can be drawn. The consultant must use his discretion, but the general practitioner must not under the provocation of an apparent slight be too ready to look upon his brother medical man as greedy.

The lot of the young consulting physician or surgeon is not one of easy affluence. Hard work and small remuneration are his fare at the hospital. The rewards of "coaching" are in much the same proportion, and these, with perhaps some occasional fees for literary work, must be in many cases for years the main sources of income for the man without private means till time and experience bring practice. In the case of a young surgeon there is often opportunity for assisting a senior by paying a visit for him after operation or perhaps performing some of his less grave operations in his stead, and to this extent the young surgeon is better off than the young physician. Moreover, the value of a physician's opinion grows with his age, but that of a surgeon's dexterity does not to the same extent. He cannot dispense with experience, but when the diagnosis is certain a light burden of years may be to his advantage. Consequently a young surgeon may be sought after, but rarely a young physician. If the general practitioner recognised that the consultant was often engaged in every whit as keen a struggle for existence as himself he would not be so quick to find fault with him. But, on the other hand, it must be pointed out that on several occasions, when the relations of the general practitioner to the consultant have been submitted to our consideration, we have found the consultant to have been heedless of the fact that the patients in question were at the time the patients of another medical man. This is altogether wrong.

◆

# Small-pox and Vaccination.

THE Hunterian Society may be congratulated on the success of the meeting on Nov. 13th, 1901, the proceedings of which we have already published in THE LANCET.[1] The subjects under discussion were Small-pox and Vaccination. Dr. J. MACCOMBIE's paper on the Differential Diagnosis of Small-pox will be found of great value to medical practitioners in London at the present time. We have referred several times to certain points which Dr. MACCOMBIE lays stress upon, such as the modifications in the eruption of small-pox brought about by previous vaccination; also to the fact that, owing to the decrease of small-pox in recent years due to the general manner in which vaccination has been taken advantage of by the better-educated and more reasonable section of the community, many practitioners have had but very slight experience in the diagnosis of the disease. Dr. MACCOMBIE, however, draws attention to other symptoms upon which he bases a diagnosis of small-pox. He mentions the pre-eruptive stage in which difficulties often occur in connexion with prodromal rashes which may simulate those of scarlet fever and measles. He considers that circumscribed punctate prodromal eruptions showing on the groins, the sides of the trunk or the lumbar regions, or on the flexures of the arms and legs, or morbilliform or patchy non-punctate erythemata affecting usually the extensor surface of the arms, the hands, the legs, or the feet, if the initial symptoms of small-pox be present, are often sufficient warranty for suspecting the onset of small-pox and for taking measures accordingly. It is also important to remember that small-pox prodromal rashes are extremely rare in persons under 10 years of age, whilst the majority of cases of scarlet fever and measles occur under that age. In discussing the nature of the specific eruption Dr. MACCOMBIE maintains that the diagnostic points between chicken-pox and small-pox (in the differential diagnosis of which mistakes are frequently made) are the following: (1) the distribution of the eruption; (2) the shape of the vesicles; (3) the rate of growth of the vesicles; and (4) the unilocular character of the vesicles of chicken-pox compared with the multilocular nature of the vesicles of small pox. Dr. MACCOMBIE in concluding his paper draws attention to another point of great importance, namely: In what way can the present prevalence of small-pox be best utilised for the purposes of medical education? We thoroughly agree with him that it is desirable that the Metropolitan Asylums Board should recognise its responsibility and its duty in this matter and we trust that it will speedily utilise to the fullest extent the small-pox material at its disposal at the wharf and at the hospital ships for the clinical demonstration of that disease to students and practitioners.

Dr. MACCOMBIE likewise read a communication upon Vaccination in which he brought forward statistics clearly proving the immunity of recently vaccinated individuals from small-pox. He maintained that in his experience the severity of an attack of small-pox in vaccinated subjects bears, as a rule, a distinct relationship to the quality of the vaccination scars. This is a point upon which sufficient emphasis has not been laid. The case-mortality per cent. derived from a study of 11,724 cases of small-pox in vaccinated subjects shows very clearly that four or more good marks confer a much more certain protection than does one indifferent mark, the percentage of deaths varying from 2·7 per cent. in the former class to 16·7 per cent. in the latter. In all his large experience Dr. MACCOMBIE has never seen a case of small-pox in a person who had been efficiently vaccinated—meaning by this term a person who showed one-third of a square inch or more of well-foveated primary vaccination surface and who showed also marks of revaccination. This is evidence that cannot be successfully controverted by platform faddists who have probably never seen a single case of small-pox. Dr. MAJOR GREENWOOD read a paper upon Vaccination, regarding the subject principally from the point of view of the enforcement of its performance. We agree with him in his statement that boards of guardians ought to have nothing to do with the administration of vaccination laws. If the enforcement of these laws is to be entrusted to any local authority it should be to the borough council, to the health department of which it naturally belongs, and we thoroughly endorse the proposal that it would be better to place the enforcement of vaccination under the control of some central authority not likely to be influenced by local prejudice. Dr. W. ARTHUR BOND also submitted a communication upon Vaccination, in which he showed that in London during the past 10 years (1891 to 1900) of the vaccinated of all ages the percentage of deaths of those attacked was 3·1, of the unvaccinated it was 18·8. In the discussion which followed the papers we have named several speakers took part and some useful information was elicited.

The meeting of the Hunterian Society was an opportune one, as the present outbreak of small-pox shows no sign of decrease. It is perfectly useless to argue with that class of the community who pose as anti-vaccinationists; they are entirely deaf to the voice of reason. The statistics, however, brought forward at this meeting were very convincing and deserve wide circulation. We would take this opportunity of protesting against the manner in which the small-pox returns are published in the daily press. We do not refer to the number of admissions, but to the statement as regards the number of deaths. A certain number of patients are stated to have died during the week; of these some are returned as vaccinated and the others as non-vaccinated, the number in the former class being nearly always greater than in the latter. This mode of expression is very misleading and calculated to do an immense amount of harm to the cause of vaccination. It surely would not give much extra trouble if the number of patients who showed vaccination marks were divided into classes—those who had been recently vaccinated and those who had not been vaccinated within 10 years. The return of the number of deaths would then be of some real use as demonstrating the efficiency of revaccination, although naturally information of greater value would be secured if an elaborate classification could be given, stating the ages of the patients who had died, the time which had elapsed since they had been vaccinated, and the character of the marks. Doubtless such statistics will be forthcoming in the future, but it would be better to refrain from any classification than to continue the method which is now adopted.

# The Reorganisation of the Army Medical Services.

In the interval which has elapsed since the publication of the report of the committee appointed by the Secretary of State for War to consider the reorganisation of the Army Medical Services, the subject has been discussed from every point of view, and with a result which must have been disappointing to the War Office authorities. The report has, on the whole, been severely and adversely criticised, and we can only hope that the objections which have been urged will be very carefully and impartially considered before any new warrant for the Army Medical Services is drawn up finally. It is surely time that, in the interest of all concerned, these services should be placed upon a satisfactory footing and that an end should, if possible, be put to a contention which has been going on for so many years. We have had the assurance of Mr. Brodrick's desire that the British army should have the best medical service in the world, and we have likewise had the assurance of some eminent civil members of the committee of experts that the War Office inquiry was deliberately undertaken in this spirit. It need scarcely be said that no one cares to identify himself with failure, but such will, it is to be feared, nevertheless prove to be the case if the proposals of Mr. Brodrick's Committee be adopted as they stand at present. As we pointed out at the time the committee was constituted, the initial mistake was made of not having an army medical officer of high rank, ability, and experience appointed to serve upon it.

The present seems an opportune time for calmly and dispassionately reviewing the situation as it now stands That the aim, object, and intention of the scheme outlined in the committee's report are good we do not question, and that it contains many excellent points we freely admit, some of which especially benefit the officers of the Royal Army Medical Corps, while others are in the interest of the whole army. There is a plain recognition of the principle of selection for promotion as opposed to the dead-level one of seniority; increased opportunities are held out for professional study and for rewarding scientific or professional attainments; the establishment of a medical staff college in London is a proposal which has many obvious advantages; increased rates of pay for medical officers generally are recommended, together with the institution of specialist and hospital charge pay; brevet promotion is to be given for distinguished service; the temporary attachment of a medical officer to a regiment and more fixed tenure of appointments in future and less foreign service all should make for good; increased facilities are granted for retiring with a bonus at different periods of service; and the rate of pay of the Director-General, as head of the Army Medical Service, is to be raised in order to make it more commensurate with, and worthy of, his position and responsibilities. The step which has since been taken to give him a seat on the Council and Army Board is so manifestly right as to need no argument in its support. On the other hand, without criticising in detail the new scheme of army medical reform as foreshadowed and outlined in the committee's report, we may consider some of its blots and shortcomings. There is the uncertainty, to put it mildly, about a medical officer's right to retire, as at present, on £1 a day after 20 years' service. Although we do not believe, as we have already said, that there is really any intention of revoking an existing privilege without offering any compensatory advantage in lieu thereof, still the matter should be made quite clear as far as it affects medical officers now serving. To render a medical officer liable to be retired compulsorily after serving 18 years with a gratuity of £2500 is so clearly to make his position financially worse instead of better than it is now under existing regulations that we need not stop to argue about it. The terms, too, relating to the examination and optional or compulsory retirement of medical officers after having served six years in the rank of captain require to be made clearer than they are at present. A large number of medical officers serve with British troops in India, and the report of the committee leaves us somewhat in doubt as to what will be their exact position and pay in that country; but we assume that this is owing to the fact that the Indian Government has first of all to be consulted and its assent to any scheme obtained.

As to the *chevaux de frise* of examinations proposed to be placed in the path of the army medical officer during his career in the service, such a course could not fail to be distasteful and unpopular. There are those who regard a system of examinations as a very inadequate test at the best, and in the case in question as unnecessary. If it be urged that it is the usual, and indeed only available, test, then we have to say that the committee do not seem happy in their repeated application of it. As regards the Advisory Board we confess that we have grave misgivings from a business point of view as to the workability of so large and mixed a board charged with so many functions. Take, for example, army sanitation in all its branches, including the consideration of plans for barracks and hospitals, and questions of sanitary engineering. We see no objection—on the contrary, it is most sensible—to have such a board to advise on all questions affecting the education and training of medical officers, and the application of systems of hygiene to army life and practice, and so forth; but the less such a board has to do with all matters properly coming within the province of the military officials the better. Assuming that it was for many reasons deemed necessary to keep the medical service and its headquarters always in close touch with the civil profession and the medical schools, this could have been accomplished by the selection of two or three civilians of acknowledged reputation and standing in the medical profession (with power, whenever necessary, to consult any eminent specialist in any branch of medical science they liked) to act as members of the Advisory Board.

It is possible that Mr. BRODRICK, while acting in the spirit and adhering to the lines and principles which he had doubtless laid down in his own mind for his guidance, might have saved himself and the committee over which he presided from several rocks and shoals if he had studied the articles that appeared in our columns and had adopted some of the points embodied in the scheme which we outlined.[1] Let us take the subject of examinations by way of illustration. The candidate's professional qualifications, the posts and offices that he has held, and the character which he brings with him from his hospital and medical school should be a sufficient guarantee of professional fitness for the army. It will be seen that we proposed, for reasons which we assigned, to abolish the present entrance competitive examination as unnecessary and in substitution thereof to institute an examination, say, after about 10 years' service. This examination was to be of two kinds. First it was to be a pass examination by which an officer could show that he had kept himself reasonably acquainted with the progress of surgery, medicine, and hygiene—the tests to be made as practical and pertinent to army service and army hospital requirements as possible. Second, there was to be a voluntary honours examination in subjects to be selected by the candidates themselves, the range of subjects embracing surgery in all its branches, medicine, epidemiology, bacteriology, and hygiene. In the case where a man selects his own subjects it may fairly be assumed that he has given time and attention to the special study of them and he would expect the examination test to be a severe one. A separate list should be kept of the honours men and their names should be marked with an asterisk in the Army List. With this information, with the officers' records of service, and with the reports received from time to time about them, the head of the medical service should have no difficulty in selecting the best and most suitable men to fill different posts.

In the series of articles to which we are referring we may add that the following subjects were considered:—leave for special study at home or on the continent of Europe, the provision of an army medical school in London, the practical training of medical officers at military manœuvres, the increase of the army nursing establishment and the better training of hospital orderlies, the greater utilisation of civil hospitals, the introduction of an army dispensary system, the formation of an army sanitary corps for field service, the question of field medical transport, and the provision in time of peace of a large and duly registered medical reserve to be drawn from the civil element of hospitals in this country and the colonies on the outbreak of war. The whole question of providing a first class medical staff for an army is in reality a much more comprehensive and difficult one than is commonly supposed. We are aware, of course, that the report of the War Office committee in its present shape is necessarily incomplete and only supplies the loose framework of a scheme. It cannot have been intended as final and a number of subjects have been purposely left untouched by it—such as, for example, the points raised by Professor A. OGSTON. All these have still to be considered before any complete system of reconstruction can be formulated. But the aim and spirit of the committee's report are good and it contains many excellent points. Indeed, that it is capable of being so remodelled and modified as to fulfil its purpose we think possible. It rests with Mr. BRODRICK to effect this.

# Annotations.

"Ne quid nimis."

## IS THE COAL-SUPPLY OF ENGLAND SERIOUSLY DIMINISHING.

THE possibility of England being one day without coal affects the interests of every Englishman, for if England's coal-supply can be shown to be within even a measurable distance of coming to an end one of the prime factors profoundly concerning her supremacy and prosperity is threatened with removal. Yet that there is reason for some anxiety on this point is evident from the fact of a Royal Commission having been just appointed to inquire into the extent and available resources of the coal-fields of the United Kingdom and the rate of exhaustion which may be anticipated. We are glad to note that this Commission exhibits a very strong composition, experts in every branch of the question, technical, economic, and scientific, being adequately represented. All previous speculation, based chiefly on geological considerations, can no longer be counted as safe to rely upon because the rate of exhaustion has considerably exceeded the broadest calculations. The output in 30 years has more than doubled and if the views of some be correct as to the extent of the fields the coal at present in sight will have been exhausted long before the lapse of the present century. There can be little doubt that there is abundant room for improvement in regard to utilising the real value of coal as fuel. An immense waste of coal occurs through defective means of burning it. Our London fogs are proof of this and if further evidence is needed we have only to inspect the sea-shore, which in places contiguous to shipping traffic will be found strewn with small pieces of unburnt coal besides cinders still possessing value as fuel. It has been said that there must exist beneath the Atlantic and in a straight line between New York and Liverpool a huge bank of coal cinders and ash, pitched overboard by the liners, sufficient to form a bank for railway purposes. The question of how far coal can be more economically burnt, that is, how better its value as fuel can be realised, should prove to be one of the most interesting subjects for the consideration of the Commission. Meanwhile, is it possible that some new source of energy and power will be found? We know what great natural forces exist around us, but our power to utilise them is at present *nil*. The tides, the winds, the sun, all represent forces of enormous magnitude; but how can they be turned to practical account? There is little doubt that some day this will be accomplished, and it is probable that the agency will be electricity. Energy at present is derived with extreme extravagance. Steam represents but a tithe of the available force of the coal producing it and electricity still less. If coal could be translated directly into electricity without the intermediate stages of burning, raising water to boiling-point, converting it into steam, using the steam in an engine, and attaching an engine to a dynamo, an ideal way of realising its value as fuel would be attained. If, however, the coal-supply should fail, to what new source of energy and force shall we turn? It is difficult to supply the answer except by assuming that new or economical and practicable means will be discovered by which the great natural forces may be utilised. The proceedings of the Royal Commission on Coal will be followed with the greatest interest.

---

[1] THE LANCET, April 27th, 1901, p. 1224.

## THE CHEMISTRY OF THE NEW POSTAGE-STAMPS.

THE nature of the colouring matter used for distinguishing the values of postage-stamps is, as we have pointed out before, a matter of some importance, for, however dangerous the dirty practice of licking stamps may be proved to be the convenience of possessing a moist tongue for the purpose cannot be resisted by most people. That the habit has its dangers is no hypothesis. Blood-poisoning has without the slightest doubt been traced to licking an infected postage-stamp, and the chances of a postage-stamp becoming infectious are obviously abundant. We may at least expect the postal authorities to avoid as far as possible the use of doubtful colouring materials on stamps and we have reason for believing that considerable care is exercised to secure this desirable result. This year it was decided to revert to red as the distinguishing colour of the penny stamp, and all the new stamps bear the portrait of His Majesty the King. In the particular instance of the new penny stamp the colour, as we find by experiment, is admirably adapted for the purpose. We have been able to recognise it as one of the innocuous aniline reds, which is peculiarly resistant to atmospheric action or the action of moisture. Indeed, strong acids disturb it but little. We could find no injurious matters present, no irritant or metallic poison. The new halfpenny stamp, we find, is coloured with similar innocent materials to those which we found on a previous occasion.[1] The adhesive material is dextrin or British gum in all instances. From a chemical standpoint, therefore, the postage-stamps are not likely to prove poisonous, although in giving this opinion it is well to reiterate that infection from septic matter must always remain a strong possibility (when it is considered how postage-stamps are handled and how they are left lying about, frequently under an undesirable environment), so long as the habit of licking them is persisted in.

## THE SITUATION AT THE MACCLESFIELD INFIRMARY.

A SPECIAL meeting of the governors of the Macclesfield Infirmary was held on Dec 23rd, 1901, to consider a motion to be proposed by one of the governors, Mr. W. R. Brown. The gist of this motion was that the governors were regretfully compelled to give notice to Miss Clarke to terminate her engagement as junior house surgeon within four weeks from that date and that she should be offered a year's salary as a solatium. Mr. Brown, in introducing the motion, said that the governors might feel some surprise thereat, but he felt that there was no course left but to concede the terms of the honorary medical staff. He denied that they were fighting the question of women *versus* men as doctors. The governors, he said, had done nothing but what was within their right, but the medical men took offence because the governors had ignored their views. Now the governors had to retreat, because of their helplessness in face of the impregnable unity of the medical profession. Mr. Brown admitted that the medical men had not said all that they might have said in justification of their action; nor had they left the institution in the lurch, but had maintained the traditions of their profession in attending to the sick and poor in the infirmary. The proposed motion was seconded by Alderman Pickford. A governor suggested as an alternative policy that a lady, Miss Ross, be invited to accept the post of consulting physician at the infirmary. The mayor, who was presiding over the meeting, then read a letter containing a suggestion that a lady doctor should be kept on for duty amongst the women and children Other governors spoke against the proposed motion, which when put resulted in 3 voting for it and 6 against, while 2 remained neutral. Mr. Brown's attempt to deal with the position therefore failed. But on Monday, Dec. 30th, another special meeting of the governors was called by the mayor, at which he was able to announce that Miss Clarke had resigned her position, placing herself unconditionally in the hands of the governors. The resignation was accepted and the mayor proposed that a year's salary should be paid to Miss Clarke as solatium, but there being some doubt as to the legality of such a proceeding the governors agreed to subscribe amongst themselves the sum of £100 as a testimonial for her. As a result of Miss Clarke's action the medical staff will withdraw their resignations. Mr. Brown is to be complimented upon his practical attempt to bring about a solution of the difficulty. He worked, not in the interests of the honorary medical staff, but in the interests of the infirmary, and this is exactly what he should have done, being a governor, while it is exactly what a majority of the governors would not do. There seems but little doubt that Mr. Brown's action has resulted in precipitating a settlement by causing the junior house surgeon to reconsider her decision not to resign which, if maintained, would have been most unfortunate. We sympathise deeply with Miss Clarke. She was placed in an entirely impossible position by the governors, who, in their desire to run counter to the medical staff, took up an attitude which they could not maintain.

## A FRENCH APPRECIATION OF MISS FLORENCE NIGHTINGALE.

THE writers of the first French work which has hitherto been published about nurses[1] have done full justice to the pioneer of the great nursing movement which within contemporary memory has from small beginnings assumed such gigantic proportions. It is to Miss Florence Nightingale, they say at page 135 of their book, that the whole world is indebted for the introduction of sick-nursing as a profession for educated women, her authority dating from the remarkable work which she accomplished in the British Crimean ambulances. Born at Florence in 1820, Florence Nightingale was delicately nurtured and she received a careful education. But early in life the unhappy lot of the sick impressed itself so vividly upon her mind that the attractions of society at once and for ever lost all their charm She forsook the polite world and determined to see for herself if it were not possible to alleviate suffering by the exercise of intelligent care. When no more than 25 years of age she undertook a journey to the continent in order to study the nursing systems prevailing in the best known institutions for the relief of disease. Amongst others she visited the Filles de la Charité de Saint-Vincent de Paul at Paris and the Deaconesses at Kaiserwerth, and even acted as an assistant in each of these establishments. The devotion of the Sisters and the perfect order that reigned under their auspices excited her admiration but did not entirely satisfy her. Technical knowledge was urgently required in addition, and also freedom from the monastic trammels so hostile to scientific progress For nine years Florence Nightingale gave herself up wholly to the exhaustive study of her subject, which she systematically divided under three heads—the needs of the sick, the qualities and requirements of sick attendants, and the essentials of hospital construction It is no wonder, therefore, that she should have proved herself capable of completely transforming the British ambulances in the Crimea and of thereby reducing the mortality from 60 to 2 21 per cent A member of the French Academy[2] once ventured to say that it was owing to the advice of the chief medical officer of the French troops that the success of Florence Nightingale was due, but this statement is utterly and entirely unjustifiable From the first it was demonstrable that the young English "lady in chief" could reorganise and manage hospitals after so improved a fashion that the renovated establishments became in reality refuges for the sick and wounded, and were no longer deserving of condemnation such as that which was pronounced by Dr Uytterhœven who, on hearing of the death of 67,000 French soldiers while under treatment, felt constrained to exclaim "These hospitals are but ante chambers to the cemetery" But, great and glorious though it was, the work of Florence Nightingale in the Crimea is surpassed by her achievements in her own country, where she completely revolutionised the hospitals and infirmaries, opened up the nursing profession for ladies of gentle birth, and established schools for nurses The fact that in the United Kingdom at the present time there are no less than 505 of these schools will serve to show the magnitude of the results which have attended on the labours of Florence Nightingale The authors of "Les Gardes Malades"—of whom one, it may be mentioned, is a medical woman—have paid due homage to the eminent lady whose "Notes on Hospitals" are still most valuable to the architect, the engineer, and the medical officer, but they make no mention of the statesman who gave effect to her recommendations and threw himself heart and soul into the work of sanitary reform The name of Sidney Herbert, first Baron Herbert of Lea, should never be omitted when the history of sanitation is discussed

## URÆMIA AS A CAUSE OF ACUTE DELIRIUM

URÆMIA has long been known to be a condition capable of producing slight cerebral disturbances such as temporary attacks of giddiness or momentary loss of speech or of consciousness In the *Archives de Neurologie* for December Professor A Cullere of Lyons refers to the recent view expounded by Dr Carrier at the Congress of French Alienists and Neurologists held at Limoges in August, when he presented a remarkable report on insanity of uræmic origin, showing that acute mental disorder may be the outcome of uræmic poisoning Professor Cullere has recently had under observation two cases which appeared to confirm the above view and to throw light on this important question Case 1 —The patient was a woman, aged 55 years, who was subject to hallucinations and delusions, under the influence of which she persistently refused food so that she had to be fed by the œsophageal tube She was slightly febrile when she came under the care of Professor Cullere in April, 1897, and was suffering from a profuse and fœtid diarrhœa Her condition was so serious that saline transfusion *(serum de Cheron)* was employed Slight improvement resulted and her ideas, which hitherto were confused, gradually began to become clear In May there was a recrudescence of symptoms with fever, delirium, and diarrhœa as before She passed into a low typhoid condition, a bed sore developed over the sacrum, and she died in a state of coma The necropsy revealed the following conditions The lungs were normal, the heart was slightly fatty, the kidneys were small as the result of atrophy, the cortical substance being congested, granular, and contracted, and weighing not more than 80 grammes There was no macroscopic lesion of the cerebral hemispheres, but an unusual abundance of cerebro spinal fluid was present in the skull Professor Cullere considers that the attacks of acute delirium in this case were associated with the chronic nephritis which was in progress and that they were therefore of uræmic origin The diarrhœa also, in combination with the other symptoms, probably indicated a uræmic condition of the system Case 2 —The patient was a man aged 41 years, with a family history of melancholia and suicidal propensities in both the maternal and paternal branches He was of temperate habits He became insane, the mental disorder taking the form of maniacal excitement, incoherence of speech, and religious utterances He then passed into a condition of apathy with mutism and refused to take food He was thin, pale, and haggard, with very fœtid breath and obstinate constipation The pulse was soft and slow, the beats being 50 per minute or less For several weeks his attitude and manner were those of katatonia, marked by contortions, grimaces, and persistent poses indicative of fear and repugnance Four months later this state was succeeded by a melancholic phase with suicidal impulses His insanity lasted 16 months, at the end of which time he began to improve and finally recovered Nine years afterwards, in June, 1897, he had a fresh attack and was admitted under treatment with melancholia agitans and violent impulses to homicide and suicide He refused food, became feverish and passed into a state of prostration with restless muttering delirium, algidity, and coma ending in death Anuria and frequent vomiting marked the later stages The symptoms all pointed to uræmia Professor Cullere believes that the katatonic symptoms with attitudes of ecstasy and catalepsy were due to toxæmia—a view supported by Kraepelin and other modern observers Venesection and saline transfusion would thus seem to be indicated in grave cases

## SUPPLEMENT TO THE ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1900.

IN the annual report of the Factory Department of the Home Office for 1900 which was noticed in our columns some months ago[1] it was announced that a supplement dealing with the fourth and fifth annual returns of persons employed in factories in the United Kingdom would be issued at a later date We have recently received a copy of this supplement, in which Dr B A Whitelegge points out that under Section 34 of the Act of 1895 the occupier of every factory and workshop was required to make each year a return of the persons employed, and three such series of returns for the United Kingdom have already been tabulated and published It has been found, however, that the heavy and continuous labour of collecting and compiling an annual census of this magnitude not only fails to yield any results of commensurate value, but stands in the way of more practical application of the mass of material thus accumulated every year Accordingly the statutory requirement has now been modified by the Factory and Workshop Act of 1901, and in future the return will be called for at intervals not exceeding three years In dealing with the fourth and fifth annual returns of employment in 1898 and 1899 it was decided to combine them and to narrow the field and to increase the detail in directions which will be helpful in administration of the Acts. A distinction is drawn for the first time between those employés who are under and those who are over 14 years of age. It thus appears that while in textile factories the former are far outnumbered by the "half-timers" under 14 years of age, in non-textile factories the balance inclines so far in the other direction that, taking both classes of factories together, more than half of the persons under 14 years of age are employed full time. The total number of returns and also the total number of persons employed in 1898-99 were greater than in any of the preceding years. The advance was relatively greatest in Scotland and least in Ireland, while in absolute increase England and Wales head the list. As regards textile industries as a whole, the present return compared with that for 1897 shows a decrease in the numbers employed in each of the three main divisions of the United Kingdom. In non-textile factories there was an increase in each of the age- and sex-groups except female "half-timers." This increase refers mostly to gas factories, electricity-generating stations, sawmills, tanneries, quarries, glass factories, and foundries. In regard, however, to the industries in which the galvanising and finishing of metals are concerned the better separation of departments in recent occupiers' returns has to be taken into account. There was a decrease only under the heads of flax-scutching, rubber, leather, ivory, bone, shell, and jet.

## DANGEROUS CIRCULARS.

IN commenting upon the methods adopted by certain people in selling shoddy jewellery *Truth* recently referred to the practice of leaving handbills from door to door, the advertiser calling for them after a certain lapse of time. That this is not an isolated instance of a reprehensible method of advertising we have proof in the fact that a few weeks ago we found in a letter-box a ragshop circular half of which was soaked in grease and the other half covered with dirty finger marks. It was subsequently called for. We have also in our possession the circular of a marine stores dealer, a term which the wording of the circular shows to be synonymous with "ragshop keeper," bearing the words, "Please show this to the Master or Mistress and return it only to ——— when he calls." We do not state positively that disease has been spread by this practice, but at a time when small-pox and other diseases of an infectious nature are prevalent no stone should be left unturned in seeking to eliminate every possible cause of infection. Such handbills should be burnt as soon as they are found, and the man when he returns should be told that this has been done. Medical men might do a great deal by warning their patients against the danger of returning these handbills, especially when there is illness in a house, and if the measure which we have suggested be adopted it will generally be found to be effective.

## MEDICAL PRACTITIONERS AND THE SALE OF POISONS.

A LETTER which appears in another column from a correspondent signing himself "Vulneratus" sounds, we think, an unnecessary alarm. The recently passed regulation of the General Medical Council refers, so far as we understand it, to "doctors' shops" into which any member of the public can go and buy two pennyworth of laudanum or other scheduled poison. "Vulneratus," however, seems to think that it applies to medicines prescribed by medical men. The law for the sale of poisons is laid down in Section 17 of the Pharmacy Act of 1868, but in the Pharmacy Amendment Act of 1869 it is laid down in Section 3 that "nothing contained in Section 17 of the said recited Act shall apply to any medicine supplied by a legally qualified medical practitioner to his patient or dispensed by any person registered under the said Act, provided such medicine be distinctly labeled with the name and address of the seller and the ingredients thereof be entered, with the name of the person to whom it is sold or delivered, in a book to be kept by the seller for that purpose." Therefore, to our minds "Vulneratus," or any other qualified medical man, is at perfect liberty to sell or to deliver medicines to his patients containing scheduled poisons, provided that he labels the bottles, or pots, or packages with his name and address. But the Act, we take it, forbids a medical man or anyone else not registered under the Pharmacy Act to keep a shop and to supply scheduled poisons to anyone who asks for them other than on presentation of a prescription duly signed by a qualified medical man. It will be seen from the report of the meeting of the Glasgow Southern Medical Society which appears at p. 29, that the society is angry with the General Medical Council But according to the Pharmacy Acts the Council appears to have been legally right in its resolution.

## TRAUMATOL IN THE TREATMENT OF SUPPURATIVE PROCTITIS.

IN the *Gazette des Hôpitaux* of Nov. 14th, 1901, M. Suzor calls attention to the value of traumatol in the treatment of suppurative proctitis. He has used this drug for several years in the dressing of wounds; it is less odorous than iodoform and also appears to have the advantage of superiority in drying up purulent secretion and hastening cicatrisation. He reports two cases in which iodoform failed and traumatol brought about rapid cure. In one a woman, aged 36 years, who was addicted to morphia, suffered from obstinate constipation which had caused rectal irritation and for more than a year profuse suppuration. Treatment consisted in various antiseptic douches followed by iodoform suppositories. Only diminution in the suppuration resulted. Traumatol powder, about a gramme, was insufflated twice a day after administering a large enema. The result was remarkable: complete recovery ensued in eight days. In the second case a man, aged 35 years, had suppurative proctitis with anal fistula The proctitis persisted after the operation for, and relief of, the fistula. Traumatol suppositories were used, but the result was imperfect. After eight days insufflations of traumatol powder were used and the suppuration disappeared in six days.

## THE MOTOR AND THE MICROBE.

WE ordinarily count amongst micro-organisms friends as well as foes, and the former are probably in the majority. After all, we know but a few microbes which are specifically disease-producing, while we know of an enormous number which are concerned in the great economic processes of nature, working apparently in the interests of nature's higher creatures. Though a very microscopic entity the microbe possesses enormous powers consistent with its property of growing and multiplying itself infinitely. The scavenging of the world is thus the effectual work of countless microbes. The idea of microbes, however, as a source of motive power appears at first sight preposterous, but a little reflection will show that indirectly even for this purpose micro-organisms may be very intimately concerned. It is well known that if it were not for its powerful action as a drug and poison alcohol would be a cheap commodity. Sugars and starches grow in immense abundance in almost all the civilised countries in the world, and it is but a short step to convert these into alcohol by fermentation, a process due to the agency of micro-organisms. All cereals would thus serve and the roots containing sugar, such as the maple, and even fruit such as the grape, in a time of plenty might easily be a cheap source of spirit. Alcohol possesses excellent calorific value, it burns with a hot flame, it is easily vapourised, and it yields, as a rule, no deleterious products of partial combustion as does oil or coal. It is thus well adapted as a fuel for the motor-car and already motor-cars are being *run with alcohol and with very encouraging* results. The drawback to its use is, of course, its expense, but some effort to reduce this has been made with success by getting a concession from the Excise (at any rate, in France) to withdraw the high duty, which is done if it can be shown that the spirit has been rendered undrinkable. Such alcohol is known as "denatured" spirit, the addition of some highly nauseous compound making it absolutely unfit to drink whilst not interfering with its properties for the purposes of a fuel Similarly denatured alcohol is being employed in lamps for the production of an incandescent light by the heating of the Welsbach mantle in the spirit flame. It is, therefore, not chimerical entirely to suggest that the day may come when we may not only owe our increased facilities of locomotion to the much abused microbe, but some of our effectual means of artificial illumination also

## EXAMINATION OF THE BLOOD IN APPENDICITIS.

EXAMINATION of the blood does not appear to be clinically utilised in this country in cases of appendicitis The *American Journal of the Medical Sciences* for November, 1901, contains an important paper on the subject by Dr. J. C. Da Costa, jun., based on the examination of 118 cases treated by operation in the German Hospital, Philadelphia. Of these 38, or 32·2 per cent, were unattended by suppuration, while in the remaining cases this condition was present with or without further inflammatory changes. In practically every case of appendicitis the hæmoglobin in the blood is diminished; the average loss is about 30 per cent. In about 10 per cent of the cases the loss reaches *50 per cent., and in 2 5 per cent. 60 per cent. or more* The diminution in the erythrocytes is, save in exceptional cases, inconspicuous The average loss in 38 catarrhal cases was 16·2 per cent. and in 80 suppurative cases 11·9 per cent. The degree of anæmia gives no help in diagnosing catarrhal appendicitis from suppurative The hæmoglobin value of the corpuscles in the majority of cases is slightly subnormal —about 0·7 or 0 8 per cent. of the normal. The fluctuations in the leucocytes are the most important features in the examination of the blood. In the catarrhal and interstitial forms of appendicitis without abscess formation the number of leucocytes usually does not exceed normal (10,000 per cubic millimetre) and is occasionally subnormal, but sometimes counts of 12,000, 15,000, or more may be made. But in cases of abscess, gangrene, or general peritonitis well-marked leucocytosis is usually present. The majority of appendicular abscesses raise the count to from 15,000 to 20,000 or more per cubic millimetre. The average was 17,450—nearly double that of the catarrhal cases. But if the abscess is so effectually walled off that little or no toxic absorption takes place such an increase may not occur. On the other hand, in profound sepsis, when the patient is so poisoned that reaction is prevented, leucocytosis may be absent and even leucopenia may occur. But such a condition is rare; in only two out of Dr. Da Costa's 12 fatal cases was well-defined leucocytosis absent In these the counts gave 6000 and 11,200 respectively. In the other 10 the numbers ranged from 14,200 to 58,500, and averaged 19,400. The degree of leucocytosis as determined by a single examination cannot be relied upon in prognosis. If, however, by repeated examinations a progressive increase in the number of leucocytes is detected it may be concluded that the collection of pus has become more extensive or that general peritonitis has been excited. Such an accident was heralded in three cases by an increase varying from 6600 to 14,000 cells to the cubic millimetre in excess of the number previously counted Perforation is usually accompanied by an abrupt rise in the number of leucocytes, but in debilitated subjects this may be absent or even a sudden decrease may occur. In the few cases of leucocytosis in which differential counts were made the increase *was found to be chiefly due to absolute and relative increase* of the polynuclear neutrophiles, the lymphocytes, large mononuclear forms, and the eosinophiles being relatively diminished. Dr. Da Costa concludes that leucocyte counts between 10,000 and 15,000 or 17,000 cannot be depended upon in diagnosing the form of appendicitis since they may be found in catarrhal cases, but that counts of 20,000 or more almost invariably indicate the presence of pus, gangrene, or general peritonitis. Making a "conservative estimate" he finds that in one out of four cases of appendicular abscess the diagnosis is justified by the leucocyte count. In cases of operation complete emptying of the abscess is followed within a few days by a decline to normal of the number of leucocytes, if recovery is uneventful, persistence of leucocytosis after the third or fourth day following operation, may usually be attributed to undrained pockets containing pus or to general peritonitis, or to both. Hence the value of a daily leucocyte count after operation As a means of diagnosing appendicitis from the conditions most closely resembling it—ovarian abscess, pyosalpinx, ectopic pregnancy, perinephritic abscess, hepatic abscess, and malignant disease of the cæcum; examination of the blood is useless, for all the conditions just named give rise to similar blood changes But if the diagnosis lie between appendicitis and typhoid fever the former is suggested by the presence of leucocytosis, which occurs in the latter only when perforation takes place [1] Leucocytosis also excludes such non-inflammatory conditions as simple enteralgia, lead colic, ovarian neuralgia, ovarian cyst, and moveable kidney

## THE LONDON LICENTIATES' AND MEMBERS' SOCIETY.

THE constitution and aims of the London Licentiates' and Members' Society have already been described in THE LANCET (Nov. 23rd, p 1425), and we have considered the chances of successful effort on its part The society is at any rate determined not to fail for want of trying, and we hope that the next step will be fruitful. This is to be a petition to the Royal College of Physicians of London and the Royal College of Surgeons of England, begging them either to approach the governing body of the new University of London, or some other British University, with a view to obtain for the Licentiates and Members the privilege to offer themselves as candidates for the final examination for a degree in medicine, or, on the other hand, begging the English Royal Colleges to take some other independent step to remove the disabilities under which their petitioners labour. At present this petition has been drawn up by the committee of the society and is to be presented to a general meeting on Jan. 22nd The committee base the petition upon these grounds · that—

> Your petitioners find that in the practice of their profession, through inability to style and call themselves "Dr." they do labour under a very great disadvantage in comparison with the graduates of the universities of Scotland Ireland, and the provinces of England and also in comparison with the licentiates of certain of the examining bodies, and whereas your petitioners feel that they have gone through a course of professional study which is as prolonged and thorough as that laid down for the above graduates and licentiates and have passed examinations which are equal in severity and strictness to those through which the above graduates and licentiates have passed; and whereas your petitioners feel that it is to the interest of the whole medical profession that the Royal College of Physicians of London, and the Royal College of Surgeons of England should continue to attract students to the metropolitan schools; and whereas your petitioners think that the Royal Colleges can only continue to attract students to the London schools by removing the above-mentioned disabilities—

therefore they put forward this petition Without going at length into the whole question of the claim to a university degree of Licentiates and Members belonging to no university, a question in the present instance with strong

---

[1] THE LANCET, May 18th, 1901, p 1417

*pros* and *cons*, no one can fail to recognise that there is strength in the argument that the number of students in the London schools is affected by the fact that no medical prefix is obtained by passing the ordeal of the Conjoint Board. If the London Licentiates' and Members' Society can *prove* that the diminishing number of medical students at the metropolitan schools is really due, or largely due, to the fact that the title "Dr." is not obtainable through the portals by which the vast majority of London students enter the profession, then we think that the society will have a very powerful lever with which to stir the rooted convictions of the Royal Colleges. In the meantime we cannot help doubting whether the members of the society do not underrate the value of their own diplomas in the public eye

## THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope received at the Colonial Office on Dec. 24th, 1901, states that for the week ending Dec. 21st the cases of plague in the Cape Peninsula numbered 0. The cases at Port Elizabeth numbered 2, both in natives. The cases at Mossel Bay and at all other places numbered 0. The area of infection remains unchanged. The cases of plague in persons under naval and military control numbered 1, that of a native in the remount camp at Port Elizabeth. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on Dec. 27th, 1901, states that for the week ending Dec. 26th there were 38 cases of bubonic plague, of which 23 proved fatal.

## CORTICAL LOCALISATION IN THE ANTHROPOID APES.

ALMOST all the experimental evidence with regard to the localisation of the cortical centres has been obtained from observations on the monkey and lower animals, and except for the work of Beevor and Horsley upon the orang-outang no observations have been made upon the anthropoid apes. Sherrington and Grünbaum, however, as the result of some more extensive work on the same subject, have recently in part confirmed and in part modified our previous knowledge. The chief points on which these two sets of observers differ are that Sherrington and Grünbaum found that all the excitable cortex lay in front of the Rolandic fissure and no movement could be produced by stimulation of the area immediately behind that fissure, whereas Beevor and Horsley had shown that excitable centres for the elevation of the upper lip, for contraction of the opposite and upper half of the orbicularis, and for the thumb and index fingers existed in that region. Beevor and Horsley had also pointed out that small areas of inexcitable cortex existed between the excitable centres. This observation Sherrington and Grunbaum failed to confirm, and they could find no such areas in the region of the excitable cortex. They also were able to map out a centre for movements of the trunk between the arm and leg area, and, further, to localise centres for the perineal movements in proximity to the toe centre. Sherrington and Grunbaum failed to confirm the observation of Beevor and Horsley with regard to the centre for turning the head and eyes to the opposite side situated below the genu at the junction of the middle and lower thirds of the fissure of Rolando, but they fully confirmed the observation with regard to the centre for the same movement of the eyes situated far forward in the frontal region and separated from the excitable cortex by an inexcitable area. Another point in this research is suggested by the fact that in 1892 Hughlings Jackson published a "Neurological Fragment" in which he suggested on hypothetical grounds that in man the erector spinæ muscle is supplied, through the intermediation of Türck's column, by the homolateral cerebral hemisphere. The hypothesis received support from certain cases of hemiplegia in which he had observed some very slight weakness of that muscle on the side of the cerebral lesion, but it was pointed out that great difficulties attended a correct estimate of the power of that muscle. The recent work of Sherrington and Grunbaum has brought this question again into relief. Their discovery of a well-marked ventral pyramidal tract in the anthropoid apes, considered in association with their erect posture is of peculiar interest in view of the fact that in all the lower monkeys and other vertebrates such a tract is entirely absent or extremely ill-defined. Sherrington and Grünbaum, by excising the hand area in a chimpanzee, produced a temporary palsy, not only of the hand, but of the shoulder of the opposite side, and on examining the spinal cord degeneration was found in Türck's column as far as the upper lumbar region. This result is sufficiently striking when we remember the close apposition of the upper arm area to the newly discovered trunk area and the probable overlapping of all the different areas in the excitable cortex. It is unfortunate that the difficulties attending the examination of the muscles of the back are not diminished by substituting the anthropoid ape for a human hemiplegic.

## OUR LAX DEATH REGISTRATION LAWS.

AN inquest held by Mr. John Troutbeck on Dec. 30th, 1901, touching the circumstances attending the death of Patience Glossop Harris, trading as Auguste et Cie, theatrical costumiers, throws once more into strong relief the slovenly way in which deaths are registered in this country. As in all probability further action will be taken as regards certainly one person concerned, and probably as regards two, we can do but little more than mention the facts which came out in evidence. These are as follows. Miss Harris was much addicted to alcohol; she used to drink brandy heavily, together with a man named Price. This man was supported by the deceased and was also a beneficiary under her will to the extent of an annuity of £104, besides some legacies, jewels, furniture, and other bequests. Miss Harris died on Dec. 26th and was attended up to the day of her death by an unqualified practitioner named William Stanley, of 1, Portsmouth-street, Lincoln's Inn-fields, W.C. He said that he had attended Miss Harris for seven or eight years; he declined to say whether he was paid for his services, and although he stated that he had recommended Miss Harris to call in another medical attendant he declined to say whom he suggested should be called in He gave a certificate of death from cirrhosis of the liver and exhaustion. Dr. G. A. Hamerton, divisional police surgeon at Bow-street, gave evidence of what he found at the post-mortem examination. There were all the signs of chronic alcoholism and death had resulted from cerebral hæmorrhage. Edward Cox, registrar of births and deaths for the Strand district, said that he had received Stanley's certificate. He had known Stanley for many years and considered that the certificate was perfectly in order according to the Registrar-General's regulations. The jury returned a verdict in accordance with the medical evidence of Dr. Hamerton and added a rider to the effect that the attention of the Registrar-General should be called to the lax way in which the certificates of unqualified medical men were accepted as exemplified in this case. The coroner, in his summing up, pointed out how such cases afforded openings for crime and we cordially agree with him. Here is the case of a woman making a will, under which the chief beneficiary is a man who drinks with her. She is attended by an ignorant, unqualified person, who gives a certificate which is only part of the truth, which certificate is accepted, and, we are afraid, lawfully accepted, by the registrar.—It is notorious that our system of death registration is disgraceful. Even when a medical man gives a certificate he is not required to certify the *fact* of death When no qualified medical practitioner has attended, an unqualified practitioner, or someone present at the death, or the occupier of the house, or if the occupier be deceased some other inmate may give information, and such information is too often accepted, though the registrar can, if he likes, refuse a certificate for burial.

## MUNICIPAL BACTERIOLOGISTS.

THE town of Cambridge has within the last three months suffered from no less than three mild epidemics of diphtheria The municipality was greatly helped in dealing with this epidemic by Dr. Louis Cobbett of the University Pathological Laboratory, who acted as consulting pathologist At a special meeting of the Cambridge Borough Council held on Dec. 19th the Public Health Committee submitted a report stating that as in future the services of Dr. Cobbett would not be available they recommended that Dr. Graham Smith should be appointed bacteriologist to the council for two years at a minimum salary of £100 per annum with an allowance of £20 per annum for a servant and for any reasonable out-of-pocket expenses The chairman of the Public Health Committee, Alderman T. Hyde Hills, M R C S Eng., moved the adoption of the report and after some opposition, an amendment being lost by 13 votes to 21, the report was adopted. We warmly congratulate the municipal authorities of Cambridge upon the very sensible step which they have taken. They are among the earliest, although not the very first, to appoint a municipal bacteriologist, for the pioneer in this movement was, we believe, the city of Liverpool which some little time ago appointed Dr. Rubert Boyce as city bacteriologist In no disease perhaps so much as in diphtheria is early diagnosis necessary to minimise the spread of infection, and it is fitting that a municipality so intimately bound up with a great seat of learning as is the town of Cambridge should have decided to profit by the latest researches of science as this appointment shadows forth.

## THE DISSEMINATION OF INFECTIOUS DISEASE.

IN another column we publish a letter under the above heading which, so far as we can say from the facts before us, reveals a course of action by no means creditable to the hospital in question We may say that we have no knowledge to which of the metropolitan hospitals our correspondent refers, but to recapitulate the alleged facts they are as follows A woman brought her sick child to the hospital where the diagnosis was made of scarlet fever. The hospital ambulance thereupon took the mother and child to their home which consisted of one room inhabited by three other children, the room being in a house with many other occupants. The medical officer of health was communicated with and in 24 hours or so the patient was removed. If these facts be correctly stated we cannot think that the hospital authorities took the wisest course. Every hospital should have an isolation waiting-room—and, as a matter of fact, the procedure at many, if not all, of the metropolitan hospitals is to detain an infectious case, to communicate with the Metropolitan Asylums Board, to keep the patient in the isolation-room while waiting, and in about an hour the Asylums Board ambulance arrives and removes the patient. We cannot think why some such sort of programme was not carried out in the case mentioned by our correspondent. Even if the hospital in question possessed no isolation-room it would have done but little harm for the patient to wait in the courtyard or somewhere on the premises, but to send the child back to its home—a home with every facility for the spread of disease—was futile. The hospital ambulance would have been far better employed in taking the child to the fever hospital.

## COUNTY MEDICAL OFFICERS IN SCOTLAND AND THE GOVERNMENT GRANT.

A LETTER has been sent by the Local Government Board of Scotland to county councils in that division of the kingdom with reference to the conditions under which a county council will in future be entitled to obtain a share of the £15,000 contributed under the Local Taxation (Customs and Excise) Act, 1890, towards the cost of medical officers and sanitary inspectors. The new conditions come into immediate effect and are—(1) where the county council shall appoint a medical officer with permission to engage in *general* private practice no share of the grant will be allowed; and (2) in any future case of a county medical officer being permitted to engage in *consulting* practice no share of the grant will be allowed unless the Secretary for Scotland is satisfied that the circumstances are exceptional and justify the relaxation of the general rule.

## THE NEW DIRECTOR-GENERAL OF THE ARMY MEDICAL SERVICE.

IT is needless to say that at the present time the direction of the Army Medical Service requires the presence of a judicious, tactful, and strong man at the helm. From all we know of Surgeon-General W. Taylor's antecedents and of the opinion which is generally entertained in regard to him we think that the Army Medical Service is to be congratulated on his being selected for the post. That Surgeon-General Taylor is undertaking an arduous task and entering upon his appointment at a critical time in the history of the department goes without saying. Despite the difficulties which will have to be encountered in inaugurating and administering a new order of things the position is nevertheless not without some compensatory advantages which did not fall to the lot of his predecessor in office. We can only trust that any new occupant of the post may be able to turn these to account. The institution of an Advisory Board will keep the Director-General in close touch with the medical schools and profession and will enable him to gauge their feeling and opinion and on occasion to add the weight of them to that of his own. With a seat on the War Office Council, under the presidency of the Secretary of State for War, and on the Army Board, presided over by the Commander-in-Chief, he will, at any rate, have the assurance that subjects affecting his department are not discussed and decided upon in his absence. We heartily wish Surgeon-General Taylor a successful career on entering upon his new duties in the direction of the Army Medical Department

## KISSING THE BOOK.

WE have over and over again in these columns pointed out the dangers of the uncleanly habit of kissing the book of the Gospels when taking an oath Over and over again, too, have we pointed out that by Section 5 of the Oaths Act of 1888 if any witness desires to swear with uplifted hand in the form and manner in which an oath is usually administered in Scotland he shall be permitted to do so, and the oath shall be administered to him in such form and manner without further question Many persons are ignorant of this relieving clause, nay, even county-court judges have refused to allow witnesses to be sworn in this manner.[1] His Honour Judge Emden[2] and Mr. Justice Byrne have both called attention to the clause, and the former judge has caused notices to its effect to be posted in conspicuous places in his court. The Attorney-General stated in Parliament that such a notice was posted in every court,[3] if so, we cannot say that they are conspicuous. We do not believe that there is any legal compulsion for a witness to kiss the book at all, and we think it is simply a custom which has grown up no one knows how. The old form of oath was to lay the hand upon the book and to say, "So help me God and these Holy Evangels." This form might well be restored, or if such an appeal were to give offence to Scotsmen, why should not the form and manner in which an oath is usually administered in Scotland be made the form also usually administered in England? The Government might well bring in a Bill to this effect when Parliament meets. But in the meantime every witness, and more especially every medical witness, should exercise his undoubted right and demand to be sworn in the Scotch fashion.

### FEES FOR INSURANCE EXAMINATIONS.

IN our issue of Dec. 14th, 1901, p. 1710, we published a letter from a correspondent protesting against the amount of work to be done in, and the lowness of the fees paid for, medical examinations for insurance in the Century Insurance Company, Limited. Our correspondent made certain definite statements, all of which, with one exception, Mr. Henry Brown, the manager of the Century Insurance Company, Limited, directly traverses in a letter which appeared in our issue of Dec. 21st, 1901, p. 1776. The one exception is the fee, which is allowed to be 10*s.* 6*d.* Mr. Brown refers to the fact that candidates for admission to sickness benefit societies are frequently examined for less than 10*s.* 6*d.*, and that a fee of one guinea, "of course, would be impossible." We do not see any impossibility about it. Examination of a patient for life insurance is, or should be, a very responsible matter for the patient, for the examining physician, and for the company. On an average a properly conducted examination takes at least 20 minutes and may take a great deal longer. Mr. Brown and others like him seem to think that a medical man's time is of no value to him and that we should be thankful for the smallest crumbs from the tables of the wealthy. The Century Insurance Company, Limited, is, we take it, in no way a philanthropic body but a purely commercial one. Then it must pay for good work.

### SMALL-POX IN LONDON.

THE number of cases of small-pox in London shows no diminution. On Saturday, Dec. 28th, 1901, there were 40 fresh cases notified and removed; on Sunday, Dec. 29th, there were 30 fresh cases; on Monday, Dec. 30th, there were 40 fresh cases; on Tuesday, Dec. 31st, there were 42 fresh cases; and on Wednesday, Jan. 1st, 1902, there were 39 fresh cases.

THE London (Royal Free Hospital) School of Medicine for Women offers in May a Stuart Mill Scholarship of the value of £30 a year for four years. The holder of the scholarship is required to take her entire medical course at the above school and to enter into a legal agreement to practise in India under the Countess of Dufferin's fund on the completion of her course of study. Applications should be in the hands of the secretary of the school, 8, Hunter-street, W.C., by Feb. 1st.

THE Harben Lectures of the Royal Institute of Public Health will be given in King's College, London, on Jan. 13th, 14th, and 15th, at 5 P.M., by Professor Max Gruber, who has taken as his subject "The Antibodies of the Blood." Professor Gruber, who is Professor of Hygiene in the University of Vienna, will lecture in English, and all interested are invited to attend.

As we have previously announced the Prince of Wales's Hospital Fund for London will in future bear the title of King Edward's Hospital Fund for London. The work of the Fund having greatly increased and the working staff in consequence being greater, permanent offices have been taken at 81, Cheapside, London, E.C.

## Pharmacological Notes.

### THE VALUE OF THE LIQUORICE LOZENGE BASIS.

SIR JAMES SAWYER[1] has recently advocated a more liberal use of medicated lozenges in many affections of the mouth and fauces, as well as in some other morbid conditions. He also calls attention to a basis which he has found useful in his own practice—viz., the pasta glycyrrhizæ alba, or *pâte de réglisse blanche.* It is prepared like the well-known pasta althææ or *pâte de guimauve* of the French Codex, with the difference that liquorice root replaces marsh-mallow root. According to Beasley's "Pocket Formulary" the liquorice paste is prepared by dissolving gum acacia and sugar in an infusion of liquorice root, evaporating to the thickness of honey, then adding white of egg and orange-flower water, and finally continuing the evaporation until the paste is so firm as not to adhere to the hands. This paste is recommended as the basis of such lozenges as the physician may wish to prescribe in particular cases, as the active drugs may be readily combined with it by the dispenser. For example, if borax is prescribed as a local sub-astringent, detergent or antiseptic, it may be mixed with the liquorice paste in the proportion of two grains of borax to 10 grains of paste, forming a lozenge which is to be slowly sucked. When freshly made the lozenge dissolves slowly and well in the mouth and is tough enough to be in part a masticatory. This is a distinct advantage, since lozenges are generally intended to exert a local influence.

### LIQUORICE AND MARSH-MALLOW COMPARED.

The excellent suggestion of Sir James Sawyer referred to in the preceding paragraph raises the question of the therapeutic value and chemical composition of the two drugs, liquorice and marsh-mallow. The former contains an acid principle, to which the names "glycyrrhizin" and "glycyrrhizic acid" have been given, in varying proportions up to about 6 per cent.; it has a sweet taste. Liquorice root also contains a sugar and the substance asparagin. It has been used to cover the taste of nauseous medicines and is a well-known demulcent. According to Sir T. Lauder Brunton, it is particularly useful as a stimulating expectorant and when there is violent cough due to irritation of the pharynx and upper part of the respiratory passages. The same authority states that marsh-mallow root is a useful demulcent in sore-throat, coughs, or intestinal irritation. It is probable, however, that of the two drugs the marsh-mallow root is more valuable as a demulcent on account of the large percentage of mucilage that it contains, amounting to about one-fourth of its weight. It resembles liquorice in containing asparagin, and it is said[2] that the proneness of marsh-mallow root to become rancid if kept long is due to the decomposition of asparagin and the consequent formation of butyric acid. The absence from marsh-mallow root of a principle analogous to the glycyrrhizin of liquorice root is noteworthy, and on this account the marsh-mallow root is likely to be more generally tolerated in a lozenge basis, since the characteristic taste of liquorice is not universally tolerated.

### THE VARIABLE CAPACITIES OF DOMESTIC SPOONS.

It has long been recognised that the reputed capacity of spoons in domestic use cannot be depended on for medicinal use when accurate dosage is required. In this connexion C. B. Lowe[3] points out that teaspoons may vary in capacity from 75 to 130 minims Inasmuch as the teaspoon is supposed to hold 60 minims this variation is considerable and might lead to serious consequences Of the dessert-spoons examined two contained three fluid drachms and a third nearly four fluid drachms In like manner tablespoons varied in capacity from four to six fluid drachms Dessert-spoons should, of course, hold two fluid drachms and table spoons four fluid drachms Hence these domestic spoons are totally untrustworthy for medicinal use Since in actual practice few persons fill spoons perfectly full with medicinal liquids, but only approximately so, it follows that by the use of the average teaspoon (containing 107 minims) the patient would get about 50 per cent more than the theoretical quantity The average dessert- and table-spoon would give about 25 per cent more As the teaspoon is the measure by which potent liquid medicines are frequently administered this huge increase in capacity deserves attention Thus, to take an example, a physician might think that he was giving the one-sixteenth part of a grain of strychnine, whereas by the average teaspoon the patient would get $\frac{8}{72}$, or nearly one-tenth, of a grain. Or four minims of diluted hydrocyanic acid might be prescribed as a dose, but the patient would get six minims The conclusion to be drawn is self-evident—viz, that domestic spoons vary so much in capacity that it is never safe to prescribe solutions of powerful drugs to be measured by them, as a result of this the use of properly graduated glass medicine tumblers which can be obtained accurately marked should be insisted upon

# KING EDWARD'S HOSPITAL FUND FOR LONDON

A MEETING of the Prince of Wales's Hospital Fund for London (now King Edward's Hospital Fund for London) was held at York House, St. James's Palace, the PRINCE OF WALES being in the chair

*The financial report presented by* Mr J W CRAGGS was as follows —

*Financial Statement up to Dec 16th, 1901*

| | £ | *s* | *d* |
|---|---|---|---|
| Annual subscriptions | 25 655 | 12 | 5 |
| *Donations and undefined contributions* | 8 340 | 2 | 5 |
| Legacies | 5 000 | 0 | 0 |
| Annual grant from the trustees of the London Parochial Charities (for the Maintenance of Convalescent Hospitals) | 1 000 | 0 | 0 |
| Contribution from the League of Mercy | 7 000 | 0 | 0 |
| Income from investments | 5 743 | 7 | 10 |
| Sums given by donors to be invested as capital | 29 | 14 | 0 |
| Subscriptions paid in advance for 1902 | 7 | 13 | 0 |
| Special grant 1900 returned by the Middlesex Hospital | 250 | 0 | 0 |
| Making the total receipts | 53 026 | 9 | 11 |
| *Deduct the expenditure to date* | 1 530 | 1 | 6 |
| Leaves a net amount up to the present of | 51 496 | 8 | 5 |
| The balance of funds from last year is | 174 225 | 3 | 7 |
| Making a grand total of | 225,721 | 12 | 0 |

Mr CRAGGS said it should be explained that these figures were wholly exclusive of the sums received for the coronation gift The proposed awards to the hospitals would absorb all the sums collected this year without entrenching on the reserve fund

The Chairman of the Executive Committee, Mr H C SMITH, *presented the report of the committee which stated that* —

Considering the many demands made on the public in consequence of the protraction of the war it is a matter of great gratification to the Executive Committee that the total receipts up to Dec 16th have again shown an increase amounting to about £3000 over those of last year up to Dec 16th The figures therefore show continuous progress Excluding the initial start in the Jubilee year, the receipts are —For 1898 £39 272 for 1899 £48 536 for 1900 £51 549 for 1901 £52 769 (up to Dec 16th) It has been difficult to estimate the total amount available for distribution this year as the accounts for the year are not yet complete and the sum to be received from the League of Mercy was only known on Dec 16th Your committee are pleased to report the increasing success of the League of Mercy who have this year contributed £7000 being an increase of £1000 on last year's contribution £1000 more than last year, and the committee believe that this sum will be obtained without drawing on the reserve No appeals were made during the first part of the year but in the autumn your committee, feeling that the approaching coronation was a suitable occasion on which to make an effort to complete the scheme of the Royal founder and to present to His Majesty the King as a coronation gift the means of freeing the London hospitals recommended the re-appointment of an organising committee for the coronation gift, under the chairmanship of Lord Duncannon That committee is issuing various appeals The reports of the Hospitals Distribution Committee and of the Convalescent Homes Committee are appended The grants recommended to hospitals this year amount to £50 000 making with the £1000 given by the London Parochial Charities to be distributed among convalescent homes £51 000 in all The question of the heavy rating of hospitals is still engaging the attention of your committee Every hospital was visited and reported on by two members of the committee of whom one was an expert The work of the visitors proved most valuable and the thanks of your Royal Highness, as President, have already been conveyed to them The trustees of the Frank James Memorial Home have offered to the Fund the gift of the home at Cowes supplemented by a most generous endowment by Mr Arthur James and Mr William James of £10 000 to be allocated to a London hospital as a convalescent home

The following is the report of the Hospitals Distribution Committee —

The Visiting Committee have visited and reported on 85 hospitals and the Distribution Committee recommend awards to 79 Of the six left out, one is an excellent institution not in need of assistance this year the other five require either reconstruction or rebuilding and the committee hope that they will put themselves in such a position that their claims may be able to be more favourably considered next year The committee recommend this year the reopening of 34 beds now closed for want of funds making a total of 321 beds reopened and maintained by this Fund since its commencement in 1897 In the institutions which have still got closed beds there are many instances where the wards returned as closed are either used for paying patients or for nurses accommodation and some hospitals are so deeply in debt to their tradesmen and bankers that even if they had further help from the Fund it is questionable whether it would be desirable for them to incur more liabilities The committee could have employed another £10 000 this year in the reopening of closed beds had the requisite money been at their disposal The numbers of beds reopened in the different years are as follows 1897, 185, 1898, 57 1899, 45, 1900 0, 1901, 34 total 321

*The following is a list of annual grants and donations for* 1901 with the comments of the Distribution Committee —

Alexandra Hospital for Children £500, Belgrave Hospital, £500, Bolingbroke Hospital £500 British Lying in Hospital £300—£200 for Nurses Home Cancer Hospital £200, Central London Ophthalmic Hospital £100 towards rebuilding, Central London Throat and Ear Hospital £150 towards building fund Charing-cross Hospital £1[illegible]00 towards rebuilding fund Chelsea Hospital for Women, £250, Cheyne Hospital, £100 towards extension fund, City of London Hospital for Diseases of the Chest Victoria park £1500 £100—£1500 annual to support 25 beds reopened by this Fund £100 towards Nurses Home Building Fund City Orthopædic Hospital £250 £50—£250 annual to maintain 20 beds reopened by this Fund, City of London Lying in Hospital £100 Clapham Maternity Hospital £75 towards improving laundry Cottage Hospital Canning Town, £100 Dental Hospital, £100 Dreadnought Hospital £500 £500—£500 annual to meet deficiency £500 for Tropical Diseases Department East End Mothers Home £200—special to make separate labour ward on each floor East London Hospital £750—£250 towards new laundry, Establishment for Gentlewomen £75 Evelina Hospital (an excellent institution) French Hospital £100 towards improving operating theatre General Lying in Hospital £200 German Hospital £150, Gordon Fistula Hospital £50 towards repainting, Great Northern Central Hospital £750 £250—£750 annual to support 15 beds reopened by this fund Grosvenor Hospital for Women and Children £200 Guy's Hospital £5000—£5000 annual to maintain 114 beds reopened Hampstead Hospital £250 Hospital for Consumption £500 Hospital for Diseases of the Throat £100 in reduction of debt Hospital for Epilepsy and Paralysis £250—building fund Hospital for Sick Children £500 £100—£500 annual to maintain 16 beds reopened new out patient department required Hospital for Women Soho-square £2[illegible]0 £400—£250 annual to open six closed beds Hospital of St John and St Elizabeth £200 Italian Hospital £100, King's College Hospital £1000 £[illegible]50—£1000 annual to meet deficiency (advise improving lavatories), London Fever Hospital £600 London Homœopathic Hospital £[illegible]0 London Hospital £5000—£5000 annual to meet expenditure out of capital made necessary by improvements in the wards, London Lock Hospital (Female) £150—£250 towards new beds and tables, London Temperance Hospital £500 with a view to early reconstruction of out patient department London Throat Hospital (unable to recommend a grant this year) Memorial Cottage Hospital Mildmay Park £50, Metropolitan Hospital £500 £1000—£500 annual to open 10 beds Middlesex Hospital £1000—£1000 annual to meet deficiency, Mildmay Mission Hospital £200 Miller Hospital £500 National Hospital for the Paralysed £750 £750 annual to meet deficiency National Orthopædic Hospital £200 New Hospital for Women £200—£200 for painting and [illegible] floors, conditional on work being done North Eastern Hospital for Children, £500 £[illegible]00—£500 annual towards maintenance and £100 for a new diphtheria ward North London Hospital for Consumption £1000 £[illegible]0—£1000 annual to support 15 beds reopened by this Fund; North West London Hospital, £500 (well worthy of support) Paddington Green Hospital for Children £200 Poplar Hospital £100 towards furnishing account Passmore Edwards Hospital for Willesden £50 Queen Charlotte's Hospital £200 Queen's Jubilee Hospital (unable to recommend a grant) Royal Ear Hospital (to be considered next year when plans for rebuilding are definitely settled) Royal Eye Hospital £100 Royal Free Hospital £750 £750 £750 annual to meet deficiency £[illegible] towards improvements (deserving and requires more support from the public) Royal Hospital for Diseases of the Chest City-road £500 Royal Hospital for Women and Children £500, Royal London Ophthalmic Hospital £100 on; deserving more public support), Royal Orthopædic Hospital, £200 towards debt; Royal Westminster Ophthalmic Hospital, £200, Samaritan Free Hospital, £500—£500 annual towards maintenance (draw *attention to need for cutting off sanitary blocks and house* committee being increased); St. George's Hospital, £1000, St. John's Hospital (unable to recommend a grant this year); St. Mark's Hospital, £100; St. Mary's Children's Hospital, Plaistow, £250; St. Mary's Hospital, Paddington, £1000, £200—£1000 annual to meet deficiency; St. Monica's Hospital, £50 towards painting, St. Peter's Hospital for Stone, £50; St. Saviour's Hospital, Osnaburgh-street, £50; St. Thomas's Hospital, £1800—annual grant to maintain 30 beds reopened; Tottenham Hospital, £1000—annual grant to maintain 15 beds reopened by this Fund (call attention to insufficient appliances against fire), University College Hospital, £1000, £400—£1000 annual to support 25 beds reopened by this Fund; Victoria Hospital for Sick Children, £200—£100 towards isolation block; West-end Hospital for Diseases of the Nervous System, £200—£100 towards isolation wards and operating-room, Western Ophthalmic Hospital (requires rebuilding); West Ham Hospital, £300, £600—£300 annual towards maintenance (economically and efficiently worked and in a poor neighbourhood); West London Hospital, £1150; Westminster Hospital, £750, £250—£750 annual towards deficiency.

The report of the Convalescent Homes Committee was read by Mr. FRY in the absence of Mr. W. Latham, K.C., as follows:—

The committee have again followed the course adopted in previous years of making out of the limited sum at their disposal fairly substantial grants to a comparatively small number of institutions, and to *a great extent they have repeated grants to those before approved of* in preference to varying the distribution. The committee recommend the following grants —Alexandra Hospital, Convalescent Home at Painswick, £50, Charing-cross Hospital, Convalescent Home at Limpsfield, Surrey, £50; Chelsea Hospital for Women, Convalescent Home at St. Leonard's-on-Sea, £50; East London Hospital for Children, Convalescent Home at Bognor, £100, Hospital for Consumption, Convalescent Home, £50; King's College Hospital, Convalescent Home at Hemel Hempstead, £100; Mary *Wardell Convalescent Home*, Stanmore, Middlesex, £100; Metropolitan Convalescent Institution, 32, Sackville street, Piccadilly, W., £100; Metropolitan Hospital, Convalescent Home at Cranbrook, £50; Middlesex Hospital, Convalescent Home at Clacton-on-Sea, £100; Mrs. Kitto's Convalescent Home, South Park, Reigate, £50, National Hospital for the Paralysed and Epileptic, Convalescent Home at East Finchley, £50, Paddington Green Children's Hospital, Convalescent Home at Harrow, £50; Queen Charlotte's Lying-in Hospital, Convalescent Home at 20, Victoria road, Kilburn, £50, Victoria Hospital, Convalescent Home at *Broadstairs*, £50

His ROYAL HIGHNESS then moved the adoption of the financial statement and report of the Executive Committee, which, having been seconded by Cardinal VAUGHAN, was carried unanimously.

The DUKE of NORFOLK then moved a vote of thanks and of welcome to His Royal Highness for presiding on the occasion, which the LORD MAYOR seconded.

His ROYAL HIGHNESS, in responding, said: My Lords and Gentlemen,—I thank you very much for your kind vote of thanks. I should like to say that it is both a great honour and a great pleasure to me that the King should have nominated me his successor as President of his Fund for the hospitals of London, which was inaugurated by him and which after Jan 1st will be known as King Edward's Hospital Fund for London. It is unnecessary for me to say that I shall take, and do take, as keen and great an interest in the undertaking as he himself did and still does. I think we can congratulate ourselves on the general satisfactory state of affairs. I believe that this year, up to Dec. 1st, we had £6000 more than at the same date last year, notwithstanding that no appeals were sent out. An appeal has recently been made for the coronation gift alone, the accounts of which are not included in the financial statement now made as they are for this special purpose. I am glad to be able to say that we can distribute an additional £1000 this year to the hospitals of London, making a total of £50,000 altogether to the hospitals, and a further £1000 to the convalescent homes, thus making a grand total of £51,000, which, I believe, is the highest sum distributed since the first year. I am specially gratified at the continued success of the League of Mercy, which has contributed £7000 this year, being £1000 in excess of last year. I wish to congratulate Sir Henry Burdett on this happy state of affairs which I know is very greatly due to him, as well as to Lord Wolverton, Dr. Collins, and Mr. Harrison. Among those whose services have been most useful and valuable I am sure you will all regret with me the loss of my friend Dr. Creighton, the late Bishop of London, and also of Sir William Mac Cormac, that eminent surgeon. They took a very great interest in this Fund and maintained that interest until the time of their deaths. I can only say that their wise counsel and help will be greatly missed by us all. I wish to convey my warmest thanks to the General Council, and also to the Executive Committee, the Organising Committee, the Visiting Committee, the Hospitals Distribution Committee, and the Convalescent Homes Committee, the honorary secretaries, and all others connected with this Fund.

# Looking Back.

FROM

## THE LANCET, *SUNDAY, JAN.* 4, 1824.

*Medical Baths.*—Whether substances can be made to penetrate through the outer skin, this being whole and entire, is still a *sub judice* question in physiology, and until this question be satisfactorily determined, it is not perhaps possible to decide with certainty respecting the alleged virtues of materials, whether applied in a liquid or vaporous form to the surface of the body, for the counteraction of diseased states. To suppose for a moment, that the notion of medicated baths is founded in error, and is a mere expedient of empiricism, will be to excite suspicion in many readers; but every one must be aware, that faith, in different medical processes and articles, often gains for a time a very firm footing upon very slippery ground, and that maladies are not seldom cured by the unassisted influence of the imaginative power. That the bulk of the body or of a limb, is encreased by immersion in hot water or vapour, is a fact to which we have already adverted; but it has also been said, that this encrease of size is possibly attributable to other principles, than that of the actual entrance of the fluid from without, so that this *circumstance in itself would prove nothing; if, by the same* process, the *weight* of the body were increased, we should seem to approach somewhat nearer to certainty on the point in dispute. We shall again, therefore, almost immediately refer to this particular; but first, it may be right to state one or two of the leading arguments that have been adduced in favour of an imbibing power possessed by the surface of the body. That the system may be impregnated in an unequivocal manner, by the application externally of materials, as in the case of mercurial unguent, is a fact sufficiently established; and the mere *laying* some substances on the skin, even without friction, has been supposed in certain cases to give decided proofs of internal effect. It is likewise well known that thirst is often times alleviated by bathing the body in water; a practice to which sailors in long voyages often have recourse, when their supply of fresh water fails them. Dr. Macard, in his *Treatise on Bathing*, assumes this is so satisfactory in proof of absorption by the skin, that he says, "no naturalist will rate the sufferings of Tantalus very highly." The effect by others, however, who disbelieve in cutaneous absorption, has been attributed partly to the grateful sensations produced by immersion, and partly to the sympathetic relations, which the organs concerned in thirst have with the actions of the skin.

⁂ This Essay on Bathing will be concluded in our next number.

### TO CORRESPONDENTS.

Several Correspondents have expressed a wish, that the space now occupied by 'Chess Problems' should be devoted to Medical Subjects We are anxious, as far as possible, to consult the taste of our Subscribers. It must have been observed that we have already discontinued Theatrical Criticism, and other subjects of a Miscellaneous nature, perhaps to the dissatisfaction of some Readers, but we are ready to acquiesce in the above-mentioned suggestion, unless we receive such a number of Communications from other Correspondents, as may induce us to believe that a considerable portion of our Readers wish the articles on Chess to be continued.

# THE IRISH MEDICAL ASSOCIATION AND POOR-LAW REFORM IN IRELAND.

THE following circular letter has been sent to all Irish Members of Parliament:—

Royal College of Surgeons, Dublin,
23rd day of December, 1901.

To ———, M.P. for ———

DEAR SIR,—The sensational death of Dr. Smyth of Burton Port, a member of the Irish Poor-law Medical Service, also of this Association, whose heroic death in the discharge of his duty to the poor of his district has aroused public sympathy, induces the Association once more to direct the attention of Parliamentary representatives of Ireland to the many disadvantages under which the officers of the service have for so many years laboured They hope that the subject of Poor law reform may engage at the earliest possible moment the earnest attention of our legislature

It is beyond all doubt or contention that the Irish Poor-law medical service is insufficiently paid that the pittance, varying between £33 and £80 per annum, still given to medical officers in many unions bears no relationship to the areas of the dispensary districts, nor to the population contained therein, nor to the number of persons entitled to gratuitous attendance

The Association now approaches you, not alone with the view of enlisting your sympathy and interest in the welfare of its members many of whom in the past have rendered up their lives in the same heroic manner as Dr Smyth has done, but with the object of directing your attention to the following facts of great and vital importance to the health and, it may be added, the prosperity of the people of Ireland —

(a) The prevention and control of epidemics in Ireland are duties for the due performance of which the public are almost wholly dependent upon the Poor law medical officer The rate at which this official is paid (in most cases about £5 per annum) for this all important office connected with the public health is wholly inadequate to ensure its efficient discharge and is almost ludicrous when compared with similar salaries paid to English medical officers for less difficult duties of a similar character

(b) The great cost of advanced medical education and its consequent increase in value with little or no prospect of an adequate return is one of the causes of the yearly emigration of the best, ablest, and more healthily ambitious of our young Irish doctors who carry with them to our colonies, or to foreign lands those abilities which might be of such service to their fellow-countrymen at home

This is a serious matter affecting the health and welfare of the public and may become more acute if redress of these grievances is longer withheld

It cannot be expected that able medical men will continue in the future to enter a service where there is no hope of advancement and where no facilities are given for the study of those new subjects in connexion with medical science which are yearly becoming of more and more interest and utility in the alleviation of the sufferings of mankind especially when they are offered as an inducement a less wage than is given to a tradesman or a skilled mechanic

The Irish Medical Association could mention if necessary, many disabilities and hardships under which its members have at all times struggled to discharge their duty to the poor Suffice it to say that no thinking person can approach the subject of Poor law reform in Ireland without being driven to the conclusion that our grievances are real and that their redress must mean an enormous advantage to the sick poor

With these facts before you we venture to solicit your coöperation by either yourself introducing a measure of necessary reform or in furthering legislation to that end

We call upon you to provide for your own poor sick and dying fellow countrymen a physician of the very best skill and ability, not one rendered incompetent by age or bodily infirmity—not one whose declining years are soured and embittered by the thought that he must leave those dependent on him unprovided for when death overtakes him in this service of danger, hardship and distress to which the Poor law medical officer has devoted his life He must at all times be prepared to face disease and death and it is not unreasonable to ask that those who are responsible should insure that he be physically able to meet it as nobly as Dr Smyth has done

The yearly stream of emigration from our shores the yearly increase of our insane population, are subjects that must alarm our social reformers and all interested in the welfare of Ireland The housing of the very poor the sanitary education of the bulk of our people, are also matters which should be dealt with by the Legislature in its responsibilities for the betterment of our country

These weighty matters should, in the opinion of the Irish Medical Association find a place in any measure dealing with the reform of the Poor law system of Ireland

RICHARD R LEEPER F R C S Irel , Honorary Secretary

# ASYLUM REPORTS

*Saint Andrew's Hospital for Mental Diseases, Northampton (Annual Report for 1900)* —The average number of patients resident during the year was 378 and comprised 184 males and 194 females During the year 98 patients were admitted, of whom 41 were males and 57 females Of these three males and 13 females were re admissions The hospital is intended for the reception of insane patients of the middle and upper classes Mr Joseph Bayley, the medical superintendent, states in his report that the female wing of the hospital has been constantly full throughout the year, but that on the male side there has been room in the wards recently altered During the year 50 patients were discharged as recovered, or 13 2 per cent of the average number resident Of the deaths during the year, which amounted to 24 or 6 5 per cent of the average number resident, two were due to cancer, two to mania, two to phthisis, three to melancholia, three to general paralysis, six to senile decay, and the rest to other causes There has been no case of infectious fever and the sanitary condition of the hospital has been satisfactory during the year The seaside house at Deudraeth Castle has been occupied for the greater part of the year "115 patients have gone there "I hope," writes Mr Bayley, "still further to increase the number of patients who will have the benefit of a change to the seaside now that the governors have purchased Bryn y-Neuadd Hall, Llanfairfechan, which is much nearer and more easily reached than Castle Deudraeth was" Every endeavour has been made to get the patients to occupy themselves on the farm and gardens and in the shops, and with satisfactory results The average numbers employed daily comprise 73 males and 57 females The Commissioners in Lunacy state in their report that the highest praise can be given with respect to the state in which they found the institution everywhere, and that the entries in the medical case-books are made *fully* and up to date At a later visit the Commissioners record that the hospital is in excellent order, that the wards on the male side are all that can be desired, and that when the projected improvements of the wards in the female division are effected this division will fully equal the male The Committee of Management state in their report that the payments for patients are 42*s* and 25*s* a week per head respectively, according to the class in which the patients are to be placed They have recently purchased Bryn y Neuadd Hall, a mansion situated in a park of 180 acres, close to the sea, and affording accommodation for at least 40 patients Various improvements have been made with regard to electric lighting and the arrangements for boilers, heating, and stores There has been no change in the staff of officers

# VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS

IN 33 of the largest English towns 6549 births and 4233 deaths were registered during the week ending Dec 21st, 1901 The annual rate of mortality in these towns, which had declined from 21 3 to 18 5 per 1000 in the four preceding weeks, rose again to 19 3 In London the death-rate was 18 7 per 1000, while it averaged 19 6 in the 32 large provincial towns The lowest death rates in these towns were 14 3 in Portsmouth, 15 1 in Croydon, 15·9 in Halifax, 16 3 in Norwich, and 16 4 in Hull , the highest rates were 22 1 in Liverpool, in Manchester, and in Salford, 22 2 in Gateshead, and 32 6 in Oldham The 4233 deaths in these towns included 441 which were referred to the principal zymotic diseases, against 433, 418, and 414 in the three preceding weeks , of these 441 deaths 138 resulted from measles, 78 from whooping cough, 76 from diphtheria, 49 from diarrhœa, 39 from scarlet fever, 37 from "fever" (principally enteric), and 24 from small pox The lowest death rates from these diseases were recorded in Portsmouth, Bristol, Nottingham, Bradford, Hull, Gateshead, and Newcastle; and the highest rates in Bolton, Salford, Oldham, Blackburn, and Preston The greatest mortality from measles occurred in Plymouth, Norwich, Manchester, Oldham, Blackburn, Preston, and Halifax , from whooping cough in Bolton, Salford, Burnley, and Sunderland , from "fever" in Salford , and from diarrhœa in Burnley The mortality from scarlet fever showed no marked excess in any of the large towns The 76 deaths from diphtheria included 34 in London eight in Liverpool, three in Croydon, three in Cardiff, three in Leicester, three in Manchester, and three in Salford 24 fatal cases of small pox were registered in London, but not one in any other of the 33 large towns There were 538 cases of small pox under treatment in the Metropolitan Asylums hospitals on Saturday, Dec 21st, against 427, 474, and 506 on the three preceding Saturdays , 161 new cases were admitted during the week, against 123, 170 and 134 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had declined from 3353 to 3241 at the end of the four preceding weeks, had further declined to 3033 on Saturday, Dec 21st ; 247 new cases were admitted during the week, against 320, 376, and 327 in the three preceding weeks The causes of 53, or 1 3 per cent , of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham Bristol Leicester, Salford, Leeds, and other smaller towns , the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, Sheffield, and Gateshead.

In 33 of the largest English towns 4565 births and 4628 deaths were registered during the week ending Dec. 28th. 1900 The annual rate of mortality in these towns, which had been 18 5 and 19 3 per 1000 in the two preceding weeks, further rose last week to 21·1. In London the death-rate was equal to 20·6 per 1000, while it averaged 21·4 in the 32 large provincial towns. The lowest death-rates in these towns were 14·3 in Derby, 17·2 in Norwich, 17·4 in Halifax, 18·1 in Bradford, and 18·3 in Birkenhead; the highest rates were 23·5 in Birmingham, 24·2 in Salford, 25·2 in Huddersfield, 26·3 in Burnley, and 29·3 in Manchester. The 4628 deaths in these towns last week included 485 which were referred to the principal zymotic diseases, against 418, 414, and 441 in the three preceding weeks; of these 485 deaths 198 resulted from measles, 84 from whooping-cough, 71 from diphtheria, 45 from scarlet fever, 37 from diarrhœa, 27 from small-pox, and 23 from "fever" (principally enteric) The lowest death-rates from these diseases last week were recorded in Plymouth, Portsmouth, Derby, and Bradford; and the highest rates in Norwich, Burnley, Preston, and Leeds. The greatest mortality from measles occurred in Norwich, Manchester, Salford, Oldham, Preston, and Huddersfield; and from whooping-cough in Liverpool, Burnley, and Leeds. The mortality from scarlet fever, from "fever," and from diarrhœa showed no marked excess in any of the 33 towns. The 71 deaths from diphtheria in these towns included 28 in London, seven in Burnley, five in Birmingham, four in Birkenhead, four in Liverpool, and four in Sheffield. 25 fatal cases of small-pox occurred in London and two in West Ham, but not one in any other of the 33 large towns There were 665 small-pox cases under treatment on Saturday last in the Metropolitan Asylums hospitals, against 474, 506, and 538 on the three preceding Saturdays; 225 new cases were admitted during the week, against 170, 134, and 161 in the three preceding weeks The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 3241, 3188, and 3033, at the end of the three preceding weeks, had risen again to 3137 on Saturday, Dec. 28th; 263 new cases were admitted during the weeks, against 377, 331, and 320 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 470, 427, and 393 in the three preceding weeks, rose again to 425 last week, but were 176 below the corrected average weekly number. The causes of 86, or 1·9 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Salford, Leeds, and in 11 other smaller towns; the largest proportions of uncertified deaths were registered in Swansea, Birmingham, Liverpool, Blackburn, Preston, Sheffield, and Sunderland.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·5 and 20·7 per 1000 in the two preceding weeks, further rose to 21·5 during the week ending Dec. 21st, 1901, and was 2·2 per 1000 in excess of the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13·4 in Leith and 17·0 in Paisley to 27·7 in Dundee and 31·5 in Perth. The 684 deaths in these towns included 30 which were referred to measles, 17 to diarrhœa, 10 to whooping-cough, seven to "fever," three to diphtheria, and two to scarlet fever. In all, 69 deaths resulted from these principal zymotic diseases in the week, against 72 and 70 in the two preceding weeks. These 69 deaths were equal to an annual rate of 2·2 per 1000, which was 0·2 above the mean rate from the same diseases in the 33 large English towns. The fatal cases of measles, which had been 23 and 28 in the two preceding weeks, further rose to 30, of which 22 occurred in Glasgow and seven in Dundee. The deaths from diarrhœa, which had declined from 30 to 15 in the four preceding weeks, rose again to 17, and included seven in Glasgow, five in Dundee, two in Aberdeen, and two in Greenock. The fatal cases of whooping-cough, which had been four and nine in the two preceding weeks, further rose to 10, of which seven were registered in Glasgow. The deaths referred to different forms of "fever," which had been nine, 10, and 11 in the three preceding weeks, declined again to seven and included six in Glasgow. The three fatal cases of diphtheria corresponded with the number in the preceding week, and included two in Dundee. The deaths referred to diseases of the respiratory organs in these towns, which had been 186, 180, and 165 in the three preceding weeks, rose again to 188, and were 77 in excess of the number in the corresponding period of last year. The causes of 28, or more than 4 per cent., of the deaths in these eight towns were not certified.

The annual rate of mortality in the eight Scotch towns, which had been 20·5, 20·7, and 21·5 per 1000 in the three preceding weeks, further rose to 22·6 per 1000 during the week ending Dec. 28th, 1901, and showed an excess of 1·5 over the mean-rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14·1 in Leith and 17·4 in Perth to 24·2 in Dundee and 24·8 in Glasgow. The 720 deaths in these towns included 36 which were referred to measles, 23 to diarrhœa, eight to diphtheria, seven to scarlet fever, seven to whooping-cough, and five to "fever." In all 86 deaths resulted from these principal zymotic diseases last week, against 72, 70, and 69 in the three preceding weeks. These 86 deaths were equal to an annual rate of 2·7 per 1000, which was 0·5 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of measles, which had been 23, 28, and 30 in the three preceding weeks, further rose last week to 36, of which 22 occurred in Glasgow, 10 in Dundee, and four in Greenock. The deaths from diarrhœa, which had been 15 and 17 in the two preceding weeks, further increased to 23 last week, and included 15 in Glasgow, four in Dundee, two in Edinburgh, and two in Aberdeen. The fatal cases of diphtheria which had been three in each of the two preceding weeks, increased last week to eight, of which three were registered in Dundee and three in Aberdeen, The deaths from scarlet fever, which had been nine, four, and two in the three preceding weeks, rose again to seven last week, and included four in Glasgow and two in Greenock. The fatal cases of whooping cough, which had been four, nine, and 10 in the three preceding weeks, declined again last week to seven, of which six occurred in Glasgow. The deaths referred to different forms of "fever," which had been 10, 11, and seven in the three preceding weeks, further declined to five last week, and included three in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 165 and 188 in the two preceding weeks, declined again last week to 166, but showed an excess of 45 over the number in the corresponding period of last year. The causes of 27, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 18·8, 20·2, and 17·9 per 1000 in the three preceding weeks, rose again to 25·9 during the week ending Dec. 21st, 1901. During the previous four weeks the death-rate had averaged 20·7 per 1000, the rates during the same period being 19·3 in London and 19·9 in Edinburgh. The 186 deaths belonging to Dublin registered during the week under notice were 57 in excess of the number in the preceding week, and included 15 which were referred to the principal zymotic diseases, against seven, six, and one in the three preceding weeks; of these, four resulted from whooping-cough, four from "fever," three from diphtheria, two from scarlet fever, and two from diarrhœa. These 15 deaths were equal to an annual rate of 2·1 per 1000, the zymotic death-rates during the same period being 2·1 in London and 0·2 in Edinburgh. The mortality during the week from fever, from whooping-cough, from diphtheria, and from scarlet fever was considerably in excess of that recorded from each of these diseases in any of the three preceding weeks. The deaths from diarrhœa, which had been four, two, and none in the three preceding weeks, rose again to two The 186 deaths in Dublin included 28 of children under one year of age and 42 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a marked excess over the numbers recorded in the preceding week. Eleven inquest cases and 10 deaths from violence were registered, and 63, or more than a third, of the deaths occurred in public institutions. The causes of 10, or more than 5 per cent, of the deaths in Dublin were not certified

The death-rate in Dublin, which had been 17·9 and 25·9 per 1000 in the two preceding weeks, further rose to 26·8 per 1000 during the week ending Dec. 28th, 1901. During the 13 weeks ending on that date the death-rate averaged 21·7 per 1000, the rates during the same period being 18·4 in London and 18·0 in Edinburgh The 193 deaths of persons belonging to Dublin registered during the week under notice showed an excess of seven over the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against six, one, and 15 in the three preceding weeks; of these five resulted from "fever," three from diarrhœa, and two from diphtheria. These 10 deaths were equal to an annual rate of 1·4 per 1000, the zymotic death-rate during the same period being 2·1 in London and 0 8 in Edinburgh. The mortality both from "fever" and from diarrhœa slightly exceeded that recorded in the preceding week, while the deaths from diphtheria showed a slight decline. The 193 deaths in Dublin last week included 26 of children under one year of age and 63 of persons aged upwards of 60 years; compared with the numbers in the preceding week, the deaths of infants showed a decline of two, while those of elderly persons were 21 in excess Three inquest cases and seven deaths from violence were registered; and 71, or nearly three-eighths, of the deaths occurred in public institutions. The causes of 13, or nearly 7 per cent., of the deaths in Dublin last week were not certified.

# THE SERVICES.

### ROYAL ARMY MEDICAL CORPS.

SURGEON-GENERAL A. F. PRESTON, who has been acting as Director-General of the Army Medical Service, has resumed the post of Principal Medical Officer in Ireland on being relieved at the War Office by Surgeon-General W. Taylor.

Major J. R. Stuart is transferred from the Deesa district to the Bombay district, and Major A. P. H. Griffiths from the Mhow district to the Deesa district and appointed to the medical charge of the Station Hospital, Ahmedabad. Major F. S. Le Quesne, V.C., is appointed for duty with the 3rd Battalion York and Lancaster Regiment.

### VOLUNTEER CORPS.

*Artillery:* 1st Dorsetshire (Southern Division, Royal Garrison Artillery): Surgeon-Captain A. Kinsey-Morgan to be Surgeon-Major. *Rifle:* 1st Volunteer Battalion the Lincolnshire Regiment: Arthur Stanley Green, to be Surgeon-Lieutenant.

### DEATHS IN THE SERVICES.

Henry James Penny, F.R.C.S. Eng., I.M.S. (retired), at his residence at Taunton on Dec 22nd, 1901, in his eighty-sixth year. The deceased belonged to an old Taunton family and qualified M.R.C.S Eng. in 1841; being admitted F.R.C.S. Eng. in 1856. Shortly after qualifying he entered the Indian Medical Service, retiring about 30 years ago with the rank of deputy inspector-general of hospitals. Mr. Penny then returned to Taunton.

### ROYAL NAVAL HOSPITAL, HASLAR.

The session of special instruction at the Royal Naval Hospital, Haslar, terminated on Dec. 21st, 1901, when the following surgeons received appointments to H.M. ships. Prizes were awarded to Surgeon A. T. Gailleton (silver edal and books) and Surgeon T. B Shaw (microscope). rgeons in order of seniority:—

| Name. | Marks | Name. | Marks. |
|---|---|---|---|
| T. B. Shaw ... ... .. | 6014 | G. S Davidge .. ... ... | 5121 |
| A. T. Gailleton ... ... | 5731 | P. T. Nicholls ... ... ... | 4997 |

L. Crosbie (entered under special Admiralty regula-ons).

### SOUTH AFRICAN WAR NOTES.

Civil Surgeon Reid is reported severely wounded and ivil Surgeon Wright slightly wounded at Tweefontein Dec. 25th).

Lieutenant J. S. Twigg, R A M.C., is reported killed on ec. 22nd between Clanwilliam and Calvina. He joined e service in 1900.

Civil Surgeon (attached R.A.M.C.) W. E. Jones is reported riously ill.

### VITAL STATISTICS OF THE INDO-DUTCH ARMY.

The information set forth in the following table is interest- g, but its value is considerably lessened for the purposes of mparison because the system upon which the statistics are arranged is somewhat at variance with that adopted in India and in our tropical colonies.

*Indo-Dutch Army.*

| — | 1898. | | 1899. | |
|---|---|---|---|---|
| | Europeans. | Natives | Europeans. | Natives. |
| Average strength ... ... | 16,318 | 24,963 | 16,389 | 24,137 |
| Remained per 1000 on Jan. 1st... ... . .. | 115 | 66 | 123 | 74 |
| Admitted per 1000 .. | 1,960 | 1,276 | 1,727 | 1,213 |

Among the European deaths 36 took place out of hospital in 1898 and 30 in 1899, the causes alleged being as follows: fever, three; beri-beri, one; apoplexy, two; delirium tremens, two; paralysis of the heart, two; enteritis, one; peritonitis, one; hæmorrhage, one; gunshot wound (murder or accident), four; killed in action, four; died from wounds, six; exhaustion, two; drowning, 16; hanging, one; crushing, four; "fear," one; burning, six; suicide, 10; cause unknown, two. Of the deaths in hospital among Europeans, 147 are ascribed to paludism, 13 to typhoid fever, three to cholera, eight to beri-beri, one to tetanus, three to pyæmia, three to syphilis, five to debility, seven to affections of the nervous system, seven to affections of the lungs, four to pulmonary phthisis, four to heart disease, five to palpitation, four to liver affections, 54 to other digestive diseases, five to venereal complaints, two to skin diseases, and 36 to other affections, the total for the biennium being 311.

### SOUTH AFRICAN AFFAIRS.

Although we are not, of course, directly concerned with the progress of any purely military occurrences at the seat of war in South Africa otherwise than as these must affect the medical services by tending to prolong the war, it is impossible to pass over unnoticed the losses sustained by the British force at Tweefontein, owing to De Wet's fierce and determined attack. The recent disaster at Tweefontein closely resembled that which happened at Majuba Hill in 1881; essentially the same plan and tactics were successfully adopted by the Boers with very similar results on both occasions. In addition to the long list of casualties at Tweefontein, which may happily be regarded as an exceptional occurrence, there have been several minor engagements in which the British troops have successfully surprised and attacked laagers and made more or less important captures with relatively small loss to themselves. The latest sick returns are satisfactory on the whole. They show much the same amount and nature and causes of disease as heretofore. The management of the concentration camps has been taken over by Lord Milner and his civil staff. The camps are gradually being broken up with good results as far as the prevalence and amount of sickness are concerned.

### THE INDIAN MEDICAL SERVICE AND THE REPORT OF MR. BRODRICK'S COMMITTEE.

As might be expected much interest and curiosity have arisen as to how the changes foreshadowed in the report of Mr. Brodrick's Committee on the Royal Army Medical Corps will be received and carried out by the Indian Government and what effect the new scheme will have upon the Indian Medical Service Any changes and improvements in the British Medical Service will have to be adapted and made applicable to the Indian Medical Service which, it must be borne in mind, has to meet numerous civil as well as military requirements in that country. It is pretty well known that the subject has been occupying the attention of the officials at Simla and it is believed that the Indian Government has been drawing up some scheme of proposals for submission to the Secretary of State.

### THE POST OF DIRECTOR-GENERAL OF THE INDIAN MEDICAL SERVICE

The recent death of Surgeon-General R. Harvey at Simla causes a vacancy in the appointment of Director-General of the Indian Medical Service, and the Government of India, in addition to other more or less urgent matters of a military medical nature now engaging its attention, will have to select a successor to the late Surgeon-General in that post. The appointment is a very important and responsible one and it is needless to add that the selection of an able and experienced medical officer is required to fill it well. Up to the present time no official announcement has been made as to the name of the officer to be appointed by the Government.

## FIRST AID FOR PRIMARY HÆMORRHAGE: THE WRONG TEACHING GIVEN TO AMBULANCE CLASSES.

*To the Editors of* THE LANCET.

SIRS,—The practical outcome of notions stated to have been acquired at ambulance classes as regards the first aid for primary hæmorrhage has come under my notice in many cases admitted under my care at the Westminster Hospital. The result has been to increase, in some cases very largely, the amount of bleeding over and above that which would have occurred had no such first aid been applied.

It would appear that instruction is given in such classes which is not informed by the actual requirements of practical surgery. Those who have attended such classes seem to have got the idea fixed in their minds that they must always apply some sort of an improvised tourniquet to the limb above the bleeding point, whilst they have not learned in these classes the necessity of applying pressure directly to the wound. The uninstructed individual, retaining his presence of mind, might apply pressure directly and so in the great majority of cases successfully control the hæmorrhage until the arrival of medical help. Those who have been wrongly instructed as regards this first aid do not understand that by applying an improvised tourniquet above the bleeding point with a degree of tightness short of absolutely controlling all the circulation they directly cause venous obstruction and raise the venous tension so as to approach that in the corresponding arteries. It is thus easy for a large part of the patient's blood to be forced out of a very small wound simply as the result of the application of such a tourniquet.

Instances of entirely unnecessary hæmorrhage caused in this way have been seen by me most frequently in cases of ruptured varicose veins, superficial lacerated wounds, and compound fractures. The most absurd instances are the cases of ruptured varicose veins and varicose ulcers, for the elevation of the limb or the slightest pressure with the finger would have sufficed to stop the bleeding. To quote one. A man struck his leg against the corner of a box, causing a minute puncture, such as might be made by a tenotome, in a varicosity behind the knee. His fellow workmen tied a handkerchief round the thigh sufficiently tight to cause venous obstruction, but did not apply any pressure over the bleeding spot. This was what they said they had been taught to do. By the time the patient reached the hospital he was acutely anæmic. I saw him immediately on admission; he was infused with saline fluid and recovered, but a month later he was still anæmic. There was no further bleeding from the puncture directly the constricting handkerchief was removed.

Quite recently two men were admitted to the hospital with superficial lacerated wounds about the elbow. With other men they had been lifting a large plate of glass which suddenly broke in pieces and cut them. A bandage was at once applied in each case above the wound, from which they continued to bleed severely and were both very anæmic on reaching the hospital. A careful examination under an anæsthetic showed that only the superficial veins about the elbow had been divided. Neither the brachial artery nor its branches had been injured. The effect of the bandages applied above the wounds had been to cause a forced venesection in each case, rendering infusion necessary. The anæmia markedly delayed healing. Similar altogether unnecessary loss of blood has occurred in cases of compound fractures. In the following one I believe the improvised tourniquet to have been the direct cause of the patient's death. A strong young man, aged 20 years, sustained a compound fracture of the lower third of the femur with protrusion of the upper fragment. There was no further injury, as the subsequent post-mortem examination showed; the popliteal artery and vein, also the anastomotic artery, were uninjured. Only the muscles of the lower third of the thigh, including terminal branches of the profunda artery and vein, were lacerated. Immediately after the accident a handkerchief was tied round the thigh above the wound and the man was carried straight to the hospital. I happened to see him as he was brought in. He was then absolutely anæmic; his blood had saturated all the clothes of the lower limb. The half-tight constricting handkerchief was removed, and no blood escaping a pad and firm bandage were applied over the wound. He was then quickly infused with six pints of saline fluid, stimulating rectal enemata, injections, and drinks being also tried, but he died in about an hour. The post-mortem report says that the cadaver was exsanguine. Such a compound fracture without complications in a healthy young man is, of course, quite consistent with recovery.

The application of direct pressure is the proper first aid in all cases. The vast majority of such cases are superficial lesions of veins and small arteries. Supposing the much rarer instance of hæmorrhage from a large artery, the wound must be directly pressed upon or too much blood will be lost whilst a tourniquet is being improvised. First aid has been successfully rendered—e.g., by army medical officers—either by pressure with the bare finger or along with the interposition of a plug, directly upon the cut artery. It must surely tend to confusion if in an elementary ambulance class the teacher enters upon the subject of the circulation and the compression of the main arteries. One hears about ladies being taught to compress the femoral artery of a little boy, but are they told at the same time how difficult this would be to accomplish in an excited and restless adult—a muscular man, or fat woman?

When told to use improvised tourniquets is it explained to the class how tightly a surgeon has to apply an elastic band even on an unconscious patient to control fully the circulation? Supposing a tourniquet to be applied really tightly to a conscious patient, such pain is caused that the patient will wriggle and try to push the band a little lower down the limb, so slackening it. It may be argued that pressure should first be applied to the bleeding point and then an improvised tourniquet made to encircle the limb above. The most probable result, say in the case of deep hæmorrhage from a puncture or bullet-wound, will be to raise venous tension in the limb, and the blood being prevented from escaping by the wound it becomes widely extravasated into the limb and this may lead to gangrene and amputation. In conclusion, therefore, I desire to point out that instruction in first aid for primary hæmorrhage which does not put direct pressure upon the wound forward as the one and only method, to be kept up until medical help comes, fails in its object. Secondly, the instruction as to improvised tourniquets shows a lack of acquaintance with the actual circumstances intended to be met. The result is the production of an unnecessary, often dangerous, amount of hæmorrhage owing to venous obstruction whilst the main artery still continues to carry blood to the limb. In the cases which have fallen under my notice where an improvised tourniquet has been used much more blood has been lost than would have taken place had no such "first aid" been given.

I am, Sirs, yours faithfully,

WALTER G. SPENCER,

Dec. 30th, 1901. Surgeon to the Westminster Hospital.

## THE CONSULTANT AND THE GENERAL PRACTITIONER.

*To the Editors of* THE LANCET.

SIRS,—As a subscriber to THE LANCET for over 30 years will you allow me a small space in your valuable journal for the inclosed, with your opinion upon the same?

A patient of mine under treatment for an attack of laryngeal catarrh came to me on Friday, Nov. 22nd, at which time he was steadily improving; he also seemed perfectly happy about the way he was going on. On the Monday following he called again, bringing for me a letter. He told me that he had consulted a Dr. ——, a specialist. He informed me that he had told Dr. —— that he was under my care; also that he had come to him without my knowledge, or desire, or sanction. With this information Dr. —— saw him. He asked what my treatment had been and then suggested a line of treatment for *me* to carry out, when I had neither desired nor asked, nor sought his help I declined to receive his communication, contending that no consultant ought to see a patient under treatment without first receiving a card of introduction or some kind of communication from the general practitioner who has the case in hand My contention, further, is that such behaviour is not in harmony with the dignity of an honourable profession and would not be tolerated for one moment in her sister profession, the law A "consultant" is no longer a "consultant' but thereby enters the open competitive market with the general practitioner and all trust between two branches of an honourable profession is lost

I am, Sirs, yours faithfully,
F MONTAGUE MILLER

Upper Clapton, N E , Nov 30th 1901

## ENLIGHTENED ST LUCIA

*To the Editors of* THE LANCET

SIRS,—The efforts made by our smart, go ahead but underpaid colonial governments, and their smart, go ahead but underpaid sanitary services, to comprehend a new idea—namely, the fact that several diseases are carried by mosquitoes—have afforded during the last three years an intensely amusing spectacle, quite worthy of the Turkish Empire That progressive island, St Lucia, is a case in point. Malaria accounts for more than a fifth of the admissions, even into the civil hospitals, filariasis is common, and yellow fever is an occasional visitant Had the island belonged to the Americans it would have no doubt, long ago been treated to the anti-mosquito operations which have produced such brilliant results in Havana , but unfortunately it is only a British colony It possesses, however, two young medical men, Mr O Galgey and Dr St George Gray, who are trying to rouse the sleeping ox In the Hospitals Report for 1900[1] they have actually described the existence of anopheles pools in the island and have even suggested that anti mosquito measures "might be applied with beneficial effect to Castries and its environs," while Dr Gray has gone to such lengths as to recommend the use of mosquito nets

We can well understand the horror and amazement of the St Lucians at such revolutionary proposals That great paper, the *Voice of St Lucia*, has at once bravely confronted the medical incendiaries In its issue of Nov 14th it devotes several columns of wit and wisdom to their discomfiture Dr Gray is recommended (as Keats was) "to stick to the scalpel and put away the pen " We are told that there is nothing "more likely to discredit the mosquito theory than the special pleading of such advocates as these " Lastly, in the midst of some of the worst trash I have ever seen printed even in a colonial newspaper, it insinuates that Dr Gray, who has evidently been working hard at his subject from a proper sense of his duties, is prompted by pecuniary motives and *wishes to be paid* for disclosing the locality of the anopheles pools found by him "We are sure a small grant from public funds ' says the *Voice of St Lucia*, "would transfer this valuable information from the doctor's mind to the public domain "

The reports of Dr Gray and Mr Galgey are covered in the same official publication by a letter from Mr O Dennehy, the colonial surgeon Mr Dennehy s remarks are not very intelligible but they scarcely give to his subordinates the support which we should expect from the head of their profession in the colony All he does is to venture upon a few observations of a discursive scientific nature "The mosquito and its parasites are now beyond question proved to be the bane of tropical life," he says, "but the origin of the parasite has yet to be shown " I do not think anyone will in the least understand what this means Again, referring to the prevalence of culex fasciatus in the island, he says "Let us hope there is some mistake or false report here as we have not had a case of yellow fever for several years past '—as if yellow fever should exist wherever culex fasciatus exists that is all over the tropics And this is all , not a hint of any practicable recommendations for removing mosquito borne disease in the island

The questions everyone will ask are—Why were not the anopheles pools located two years ago? Why were not drainage or house protection or other measures adopted long since ! I suppose that there is some paid sanitary authority in the place ! Why, then, does it not do its duty ? If measures against malaria can be carried on in Lagos, Sierra Leone, New York, and Havana, why not in St Lucia ?

The truth is that the Home Government should change its policy in this matter It is useless to expect the local authorities in the majority of our tropical possessions to take any initiative as regards mosquito borne disease Frankly, they evidently do not wish to be put to the trouble The Home Government should send out explicit instructions or should take the example of the Liverpool Tropical School and despatch an expert to each colony for the express purpose of superintending anti malaria measures It is absurd to talk about want of funds If a few Liverpool merchants can afford to despatch a dozen men on such errands, as they have done, surely the British empire can afford to do the same thing It is time that more businesslike measures be adopted in this matter In the meantime I fancy that the efforts of Dr Gray and Mr Galgey will receive more appreciation in this country than they appear to be receiving in Lotos Island I should like to add, however, that we must all fully recognise the great assistance which is being given to this cause by Mr Chamberlain, Dr P Manson, and the governors of the West African colonies

I am, Sirs, yours faithfully,
RONALD ROSS F R C S Eng , D P H Lond , F R S

Liverpool School of Tropical Medicine, Dec 16th 1901

P S —Yellow fever has just broken out in St Lucia It will be interesting to see what measures the local authorities will take against it

## THE GODDESS OF SMALL-POX

*To the Editors of* THE LANCET

SIRS,—In the discussion upon small pox at the Hunterian Society reported in THE LANCET of Dec 28th 1901, it was mentioned that in India there was a goddess called ' Amma, ' or mother I have at this moment in front of me a silver plated copper figure of this very "Amma " goddess of small pox She is about two inches high, a stout, middle aged lady, kneeling in elaborately chased robes, which form a base about three inches in diameter Her face is quite clear and clean cut but the curious point about the idol is that there fits over the face and head a detachable mask and guilded cap representing another face and head prodigiously swollen and deeply pitted with pocks I shall be pleased to show it to anyone interested or to lend it for exhibition to any medical society that will guarantee its safety

I am, Sirs, yours faithfully,
40 Camden square N W , Dec 31st 1901 JOHN F J SYKES

## THE SUPRAPUBIC OPERATION IN ENCYSTED CALCULUS

*To the Editors of* THE LANCET

SIRS —In the Bradshaw Lecture delivered at the Royal College of Surgeons of England on Dec 11th, 1901, and published in THE LANCET of Dec 14th (p 1647) Mr T R. Jessop describes three interesting cases of encysted stone in the bladder in each of which the stone was successfully removed by the suprapubic operation The lecturer informs us that cases of this kind are very uncommon That they are so is amply proved by the fact of his having met with only three in his long and wide experience I happen to have seen a case of this description while practising in Australia a few years ago and as it has not been previously recorded and in respect of the size of the stone is somewhat exceptional, it may not be out of place to mention it in this connexion

The patient was a man, aged 68 years, a gold digger working on an alluvial field near Cowra, N S W , where I was then residing He came to me in October, 1895 complaining of frequency of micturition, great pain and difficulty in passing his urine, and occasional slight hæmorrhage He appears to have had symptoms of stone for six years, for during the first half of that period, so he informed me, he had been sounded for stone by well known surgeons in Melbourne and in Sydney on some half dozen occasions but at that time no stone could be detected He had then returned to the goldfields, where he remained until his sufferings became unendurable During the three years that had elapsed since the last examination the stone had evidently increased greatly in size, for when I saw him the sound came in contact with a stone immediately it entered the bladder and could not easily be passed around and beyond it. With the finger in the rectum a large calculus could be felt directly above the prostate, and its size and shape were roughly ascertained By using the sound in the bladder in conjunction with the examination per rectum the more important information was gained that the stone was firmly fixed in the floor of the bladder, for it could not be rolled over or moved from its position in relation to the prostate by pressure either from the finger behind or from the sound in front.

---

[1] St. Lucia Gazette, Castries, Nov 8th, 1901

Under the circumstances it was clear that the only way of removing the stone was by the suprapubic operation, and this the patient had no hesitation in submitting to for his sufferings were undoubtedly very great I performed the operation a few days later at the Cowra District Hospital and removed a calculus weighing a trifle over four and a quarter ounces. The stone (which I still have in my possession) is egg-shaped with flattened anterior and posterior surfaces, and is rather bigger than a duck's egg, measuring eight inches in its largest circumference. It appears to be composed of uric acid with a slight deposit of phosphates. About two-thirds of the length of the stone projected into the cavity of the bladder, but its larger end was tightly held in a sacculus behind the prostate. and it was only after enlarging the incision in the bladder sufficiently to introduce the fingers of both hands that I could disengage the stone, the constricting edges of the sac having formed two deep lateral grooves in the calculus.

The operation was in all other respects carried out in the usual way, and the patient, notwithstanding his age, made a rapid recovery, returning to the diggings five weeks after the operation. When I last heard of him several months later he had had no further trouble. I have been told by practitioners of long Australian experience that cases of stone are exceedingly uncommon in that country. I do not know whether that opinion is confirmed by statistics.

I am, Sirs, yours faithfully,

Ralph C. Bartlett, M.R C.S. Eng., L.R.C.P. Lond.

Romsey, Hants, Dec. 21st, 1901.

## THE BOYCOTT OF CONSUMPTIVES AT MENTONE.

*To the Editors of* The Lancet.

Sirs,—The recent semi-official edict of the hotel proprietors at Mentone, in the Continental Bradshaw, intimating that persons suffering from consumption would not be received as guests, has created some excitement in the Riviera and many consider this virtual boycott of invalids as an unjustifiably harsh measure. This attitude of the leading hotel proprietors of Mentone is no new thing, however, though it has not before been so uncompromisingly expressed. It must be remembered that the character of Mentone as a winter resort has materially changed in the last 20 years or so. The history of Mentone, so far as foreigners are concerned, may be divided into three distinct phases. For many years after the late Dr J H Bennett (the tutelary genius of Mentone) "invented" and made Mentone it was regarded as an invalid resort pure and simple, and in the case of consumptive patients ordered to winter abroad the choice of the faculty was practically limited to Mentone or Madeira. Its great vogue as the Mecca of the consumptive gave the place a distinctly funereal reputation, and it was erroneously supposed that the town was simply a consumptive preserve. Everyone remembers Mark Twain's witticism that but for an occasional funeral there would be no life in the place, while the famous French romancer, M. Guy de Maupassant, had much to do with the perpetuation of the "Cave of Despair" legend when he wrote: "This charming and balmy country is the hospital of society and the flowery cemetery of aristocratic Europe. How truly in every part of the world this lovely and terrible spot must be accursed, this ante-room of death, perfumed and sweet, where so many humble and royal families, burghers or princes, have left someone, some child on whom they concentrated all their hopes and lavished all their love and tenderness." Then came the second stage in Mentone's history, when it became a quiet and retired resort, much frequented by non-invalid visitors who objected to the expense of ultra-fashionable Cannes and the gaiety and bustle of Nice, the metropolis of the Riviera. For many years, too, it was the favourite resort of overworked clergy attracted by the combination of cheap living and lovely scenery.

Of late years a still more marked change has taken place. Mentone has become distinctly fashionable and consequently almost as expensive a residence as Nice or San Remo, though less so than Cannes or Monte Carlo Then its proximity to the latter place has made it popular with many frequenters of the casino who for obvious reasons prefer not to live actually under the shadow of the palace of fortune. There is no doubt something to be said for the hotel proprietors' point of view. The opinion, whether erroneous or not, now gaining ground, that Mentone is more or less a consumptive settlement would be obviously prejudicial to the interests of Mentone in general as a residential winter resort and to the hotel-keepers in particular. As a preliminary measure steps were taken to convince the public that this beauty-spot of the Riviera was not exclusively to be regarded as a Mecca for invalids. Finally, and within recent years, those interested in the hotel enterprise let it be understood that, taking a leaf out of the book of the Pontresina hotel managers (who have for many years tabooed phthisical visitors), no consumptive person would be admitted.

It must be remembered that Mentone is practically one great hotel—there are more hotels in comparison to the population than at any town in the Riviera, except Cannes and Monte Carlo. Hotel-keepers must live, and it is unquestionable that ordinary visitors will not patronise an hotel which is known to take guests suffering from consumption. Thus, to put it bluntly, as there are not enough invalids to go round, the bold alternative of mainly depending upon a consumptive *clientèle* as at Davos is impracticable.—I am, Sirs, yours faithfully,

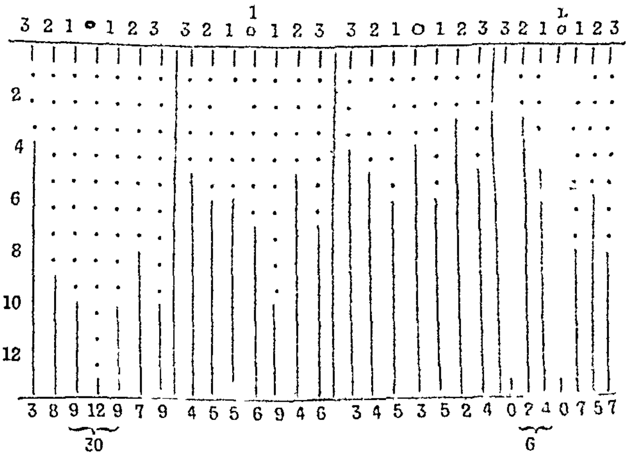
E. A. Reynolds-Ball,

Dec. 19th, 1901. Author of "Mediterranean Winter Resorts."

## WET DAYS.

*To the Editors of* The Lancet.

Sirs,—May I invite your attention to some weather facts which, I think, are not without their medical bearings? In the rough diagram herewith each dot represents a day with 0·4 in. of rainfall or more at Greenwich; and the diagram shows the distribution of such days (in the last 12 years, 1889-1900) in the week about new moon, first quarter, full moon, and last quarter respectively. Please note the following: (1) the preponderance about new moon at once strikes the eye; (2) the third day before last quarter and the day of last quarter were without cases of such rainfall; (3) while the three-day group before last quarter, and that ending with last quarter, had each six cases the three days about new moon had 30 (i.e., five times as many); and (4) it might be shown that the total number of such days in weeks about new moon is greater than in weeks about last quarter in every year of the 12 except two, when the numbers were equal. Whether these facts point to lunar influence or not



it will, I think, be interesting to notice whether the same relation persists in future

I am, Sirs, yours faithfully
ALEX B MACDOWALL, F R Met S
Ilfracombe Dec 20th 1901

## THE LATE R B ANDERSON FUND

*To the Editors of* THE LANCET

SIRS —Permit me to add a word to the appeal of Lord Stamford and Mr Timothy Holmes in reference to the R B Anderson Fund It seems a most melancholy and depressing thought that an appeal renewed at intervals over six months, made by men of the highest standing, backed up by the editors of the great medical journals and on behalf of a man who is one of the martyrs of the profession if ever there was one, should only result in the miserable sum of £80 This is both inadequate for the pressing needs of Mrs Anderson and family and discreditable to the profession

When Mr Anderson was alive, when the memory of the gross injustice perpetrated on him (and through him on the profession) was fresh, we rewarded him for his heroic endeavours to secure justice in the usual way He was looked on as a crank, a misguided enthusiast, a man with a grievance, or even worse, he was regarded with suspicion, and his motives were impugned Ridiculous as it may seem to those who knew him, I have even met people who talked of him as a ' paid agitator ' The last few years of his life were spent in anxiety and poverty I am afraid that sometimes he even had not enough to eat It is a story we as a profession can only recall with shame, but it is not too late to do something for our credit's sake

Especially would I appeal to those who take an interest in medical politics I had the honour of Mr. Anderson's intimate acquaintance and never did I meet a man to whom the honour and interests of the profession were so dear Even his own wrongs were swallowed up in his enthusiasm for the cause When the rights of the profession were assailed in his person he defended them with a courage and tenacity that nothing could shake He faced prison and financial ruin rather than compromise one jot of those rights He hastened his own death by the privations and mental anxiety incurred in fighting a battle which was not his alone but that of the whole profession We may think his conduct quixotic, that he was foolish in neglecting his family and financial interests in order to fight the battle But those of us who in his place would have been less courageous (more prudent, if you will) may at any rate honour his undaunted courage and sympathise with his family, left in very distressed circumstances Every man who reads this could afford a few shillings and I trust for the honour of the profession that the fund will not be closed at anything like its present miserable state I shall personally be glad to receive and forward to the treasurer any subscriptions which may be sent to me

I am Sirs, yours faithfully,
Cotfell House Gateshead, Dec 18th 1901   ALFRED COX

## CANCER AMONG HINDOOS

*To the Editors of* THE LANCET

SIRS,—The letter of Colonel J Maitland, I M S, in THE LANCET of Dec 21st 1901, p 1763 has re stimulated my previous intention, formed at the time that Mr C B Keetley's paper appeared in THE LANCET (Oct 5th, p 939), of refuting the statement contained therein — to wit "Hindoos (*sic*) suffer comparatively little from cancer Dr C N Saldanha, judging from his name hies evidently from the Malabar coast most probably from Mangalore, South Canara, and has had his medical education at the medical institutions of either Bombay or Madras Not having a Medical Register at hand I am unable to assert definitely I have had over three years' experience of surgical work on this coast from the north of South Canara to the south of Malabar (Cochin) and can avouch for the fact that cancer, in its general signification, is common—indeed, very common among the natives in this tract of the Madras Presidency All the various organs and tissues obnoxious to this infection were represented the penis the jaws, throat, cervix uteri breasts &c The most prevalent were cases affecting the lower jaw and the penis Colonel Maitland speaks for the Madras General Hospital, where cases from all over the Madras Presidency come for operation

Thus my local, though limited, and Colonel Maitland's general and considerably more extensive, experiences of the Madras Presidency do not bear out the sweeping generalisation attributed to Mr Keetley's informant Of course, the word "Hindoos" is employed by Mr Keetley in a very loose sense and might have passed muster 50 years ago as of sufficient scientific accuracy; but in this more enlightened twentieth century this now obsolete and vague word should be replaced by one more in accordance with our advance in anthropology Mussulmans are not Hindus yet the former are subject to the same ills as the latter The term "natives of India" would remove the objection It was a pity Mr Keetley did not refer to the annual reports of the medical institutions of India, obtainable at three or four accredited booksellers in London, before accepting the *ipse dixits* of Dr Saldanha

I am, Sirs, yours faithfully,
C DONOVAN B A M D, B Ch R U I,
Captain, I M S
Instow N Devon Dec 22nd 1901

## PERMANGANATE OF POTASSIUM IN THE TREATMENT OF DYSENTERY

*To the Editors of* THE LANCET

SIRS,—In THE LANCET of Dec 21st, 1901 Mr W B Bennett of Liverpool records a most interesting case of diarrhœa in which he finally adopted the treatment of washing out the bowel by a weak solution of permanganate of potassium I have been more than usually interested in this contribution of Mr Bennett, and I think it will be of interest to him and to your readers to know that this form of treatment was successfully adopted in connexion with a mild epidemic of so called asylum dysentery at this institution more than two years ago At the time every conceivable remedy was tried with little or no effect, but no sooner had we adopted irrigation of the bowel by means of permanganate of potassium than our cases began to improve and we had no more deaths From Mr Bennett's reference to his experience of this method of treating dysentery in South Africa it would seem as if it had been employed here prior to his South African experience It is to be regretted that these facts were not put on record earlier, but it is hoped that a short contribution on the subject will see daylight before long The plan adopted here was to wash out the bowel morning and evening, and seldom had this to be repeated after the second day In every case of severe diarrhœa with any tendency to straining we now always employ this method of treatment   I am, Sirs, yours faithfully,
P W MACDONALD, M D Aberd
The Asylum Dorchester Dec 30th, 1901

## THE BRITISH ELECTRO-THERAPEUTICAL SOCIETY

*To the Editors of* THE LANCET

SIRS,—I write to ask those who are interested in this subject to support the movement started by Mr Chisholm Williams for the formation of an Electro therapeutic Society The number of those who make use of electrical methods in medical work is steadily increasing in this country, and a society which will provide a meeting place and an opportunity of exchanging ideas should be a very useful one The list of those who have already sent in their names as supporters of the proposed society is a good one and it includes a majority of the gentlemen who are in charge of the electrical departments of the London hospitals I hope that many others who may be waiting to see how things are going to turn out will be encouraged to send in their names to Mr Chisholm Williams, 20, Bedford square, London W C, before Jan 10th or will attend the meeting to be held on that day for the formal establishment of the society

I am Sirs yours faithfully
Wimpole-street W, Dec 30th 1901   H LEWIS JONES

*To the Editors of* THE LANCET

SIRS,—The first general meeting of the above will be held on Friday Jan 10th, at the rooms of the Medical Society of London, 11, Chandos street Cavendish square London W, at 8.30 P.M., to receive the report of the provisional committee.—I am, Sirs, yours faithfully,

Bedford-square, W.C., Jan. 1st, 1902. CHISHOLM WILLIAMS.

## THE AGE OF VACCINE LYMPH.

*To the Editors of* THE LANCET.

SIRS,—It would serve a very good purpose if THE LANCET called urgent attention to the necessity for a date to be affixed to every tube of vaccine sent out by our recognised purveyors. This would be a very simple proceeding and highly proper. Of course, it requires no large stock of intelligence to see that this would condemn as useless much lymph which now filters through various sources to the too confiding practitioner. As it is, I know of nothing so unsatisfactory to ourselves and the public we serve as the present almost hopeless uncertainty of the age and consequent strength of much of the vaccine stocked and sold by secondary agents. Something ought to be done to put this matter on a fair basis.

I am, Sirs, yours faithfully,

Newington green, N., Dec. 29th, 1901. GEO. J. B. STEVENS.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Plague Epidemic: the Mortality in Bombay and Elsewhere.—Death of Surgeon-General R. Harvey.—The Famine.—Final Report of the Plague Commission.*

THE number of deaths throughout India from plague during the past week is somewhat less, the figures being 7961, as against 8431 during the previous seven days. For the corresponding week last year the deaths were only 2140. The decrease this week is chiefly in the Bombay Presidency, where 5655 deaths occurred, as compared with 5980 in the previous week. Last year there were only 560 deaths. The Punjaub returns 1646 deaths, as against 946 for the previous week and only 14 last year. Bengal returns 168 deaths, but last year, when the disease was raging in the Patna and neighbouring districts, there were 798 deaths. The province of Jummu, across the Punjab border, has become infected, but Kashmir proper is free. The number of deaths from plague in Calcutta remains about the same, but during the month of November there were 93 deaths, as compared with 81 during October. The disease is once more spreading in Bangalore, not only in the city but in the cantonment. In Bombay city there is not much change, 177 deaths being recorded for this week, as against 181 for last week, but the general mortality keeps high. The present death-rate is 52 93 per 1000. For the year 1900–1901 the death-rate of Bombay city was no less than 96 56 per 1000 by the old census and 102·25 per 1000 according to the recent one. This is three times the average death-rate before the era of plague. The infant mortality is enormous. Of 79,350 deaths 13,492 occurred among children of one year of age and under.

The news of the death of Surgeon-General R. Harvey, C B, D.S.O., has been received with deep regret throughout India. He was very popular and his ability was unquestioned. He is reported to have died from peritonitis. In accordance with his special wishes his remains were cremated and the ashes were buried in the grave of his little daughter at Simla. As Surgeon-General L. D. Spencer has previously officiated as Director-General it is probable that he will be appointed to the post left vacant by the death of Surgeon-General Harvey.

During the past few weeks the famine conditions have so far improved that at present there are only about 90,000 persons under relief. The details are: Madras, 2043; Bombay, 47,508; Rajputana, 94; Baroda, 26,283; and the Bombay Native States, 16,400.

The conclusions arrived at by the Plague Commission in its recent and final report have been anticipated by most of the authorities in India for some time. The mild measures now practised are almost entirely in accordance with its recommendations. Medical examination of travellers is still carried out in some places—for some months past at Poona—but its value has apparently been negative. The conflict of opinion between the medical and civilian members of the commission concerning administrative control is natural—the civilian members on behalf of their service being jealous of the loss of power in administration. It is not generally known in England how comparatively subordinate the medical services are in India. That they are so is proved by so many of the plague appointments being held and the reports written by military and civilian officers. The scheme for the sanitary administration of India is one of the best suggestions in the report.

Dec. 6th, 1901.

## THE ORGANISATION OF THE PROFESSION. POPULAR ERRORS IN REGARD TO CLUB PRACTICE.

(BY OUR SPECIAL COMMISSIONER.)

THE *Daily Express* has a large circulation throughout the kingdom. It is published at the popular price of one halfpenny and professes to advocate progress in every direction. Recently it published an article entitled, "Poor Men's Doctors," which bears the impress of sincerity and seems to have been dictated with the object of defending the interests of the many against the selfishness of the few. In this instance the selfish few are the members of the medical profession who, by inference, are accused of having formed a sort of oligarchy or trade union so as to fill their pockets at the expense of the poor. The case is not stated in these plain words, but that is the moral which will evidently be deduced from the description given. It might be thought that the most elementary sense of justice would suggest the advisability of taking into consideration the other side of the question. Nevertheless, there is not a single fact, not a single argument, brought forward in defence of the medical profession. In THE LANCET alone there have been hundreds of columns published on the subject, but evidently the author of the article in the *Daily Express* has not read one of these nor does he seem to have questioned any member of the various medical unions that exist in all parts of the country or to have consulted any of the numerous reports and documents which these medical organisations have issued. The publication of an *ex-parte* statement is not the way to promote the cause of progress. It can but tend to envenom the situation. True progress can only be achieved by hearing all sides and then by striving to harmonise conflicting interests. The statements of the *Daily Express* are important, not merely because they have been published in a paper which has a wide circulation, but because they echo opinions which, however erroneous, are widely held by a large though misinformed section of the public.

The *Daily Express* complains of the decision of the General Medical Council, which it inaccurately entitles the "British Medical Council," in regard to the case of Dr. R Rendall of Great Yarmouth. It qualifies as "ridiculous words" the terms "infamous conduct in the professional sense," but it has nothing whatsoever to say as to the technical point at issue—namely, whether medical men should allow paid agents to canvass for patients on their behalf. The effort, however, to put an end to touting for patients deals, we are told, "with a principle concerning the health and welfare of at least 2,000,000 persons." This is doubtless true, but it affects this great number of people in a manner calculated to protect their best interests by securing for all better and more careful medical attendance. Then follows the statement that the 2,000,000 and more members of medical clubs are "workmen who under ordinary circumstances would be unable to pay for medical attendance and would be forced to apply to the parish or to throw themselves on the bounty of benevolent societies." Fact after fact, case after case, and article after article have been published in these columns and elsewhere to prove that such a statement is absolutely false; but it is not necessary to refer to this great mass of evidence—the falsehood of the statement is clearly demonstrated by the medical clubs and friendly societies themselves, for if this assertion were true they would not so strenuously object to establish a wage-limit.

The position is very simple, the case is very clear. The darkness is caused by the perverse manner in which the real issue is systematically concealed. Medical practitioners have no objection to attending the genuine poor for one penny per week, or for less, or even for nothing. Indeed, if this were merely a financial question it would be a distinct monetary advantage to the medical profession that the poorer classes should subscribe a penny per week. Their medical attendants would then get at least a part of this penny, while in the majority of cases they would get nothing at all if it were not for these weekly payments. But, of course, this advantage disappears at once where the wage-limit is not imposed; for it is the thrifty and well-to-do artisan and the economical tradesman, rather than the very poor, who join notably the friendly societies. Surely the general public should be able to understand the very simple, matter-of-fact, business-like statement made over and over again by medical practitioners Speaking generally, the medical practitioner expects, and is willing to do, a great deal of gratuitous or underpaid work. He would like to devote as much time and attention to the patients who do not pay or only pay inadequately as to those who pay full fees, but if he is to be deprived of those patients who can afford to pay the usual fees, on what is he to live while he attends to those who cannot or do not pay? In trying to do away with this abuse the medical profession is defending the best interests of the poor. By refusing to establish a wage-limit the medical-aid organisations and clubs are robbing the poor of the full and careful attendance which the medical men are willing, even eager, to give them. There are towns where a third and, in some cases, more than half of the population do not pay any medical fees. Nevertheless, the medical practitioner must live; and, as a natural consequence of this abuse, he must make up for the loss of paying patients by an enormous increase of club patients. There are some club medical officers who have 5000 or 6000 persons down on their books; and for one penny per week, and often for much less than a penny, they must attend to those among them who are ill or, as often happens, who only imagine they are ill. What must be the inevitable result of so much underpaid work?

The public, unfortunately, do not realise to what an extent this work is underpaid, and while much sympathy has been lavished on the sweated tailor, sempstress, or docker, but little consideration has been shown towards the sweated club medical officer. Yet in the series of articles on "The Battle of the Clubs" numerous and precise facts were given. These were reprinted in a cheap popular form. They have been before the public for four or five years and have never been contradicted. As an incident in point, when dealing with the Walsall Medical Association[1] it was shown that the medical officer of that amalgamation of friendly societies paid 6115 visits and gave 13,025 consultations to the members during the year 1895. For all this work he was paid a salary of £168. The adult members paid 3*s.* 6*d.* per annum and the juveniles 2*s.*, and out of this the medical officer received but 1*s.* 1*d.* per member. As a result the pay did not on an average amount to 2*d* per visit or consultation. If, however, we add the value of the house, taxes and gas, &c., provided for the residence of the medical officer the average received for advice given at the surgery or at the homes of the patients es not amount to 2½*d.* per consultation. In regard to the se of Dr. Rendall at Great Yarmouth it was stated that e members paid 4*s.* 4*d.* a year and that 10 per cent. of this m was given to the canvasser and that another 10 per cent. as retained to cover the cost of management, so that no rge profit was sweated out of the medical attendant. But is is not the case elsewhere. At Leicester for many ars the medical officers of the Leicester Provident ispensary did not receive more than 1*s.* 9*d.* per annum r member, and at Coventry 1*s.* 10*d.*" This sum, out the 4*s.* 4*d.* which the members pay, is very far from the per cent. which it is said that Dr. Rendall obtained at reat Yarmouth. But in dealing with the Battle of the lubs at Portsmouth[2] I described the financial position of the ost popular club medical officer in the town who received e entire sum which the members subscribe. The following what I then wrote: "He calculates that he is occupied ree hours per day in his own surgery receiving club atients, and some of them are sufficiently well off to ride his surgery on their bicycles Then he has to see about club patients per day in their own homes. Altogether s club patients take up about five hours per day, and r this he receives just upon £1 per day. The disnser he has to keep and the medicine he has to supply cost him about a third of this sum. Five hours per day at £1 equals 4*s.* per hour, and deducting the cost of medicine, &c., we get a net profit of about 2*s.* 8*d.* per hour of professional work. The fee for each consultation, including medicine, amounts in this case to from 4*d.* to 5*d.*. Nevertheless, the members of these clubs imagine that their medical officers are very well paid and rapidly accumulate fortunes. This is especially the case when the medical man keeps a carriage They do not realise that a carriage costs 10*s.* a day, and that even at this price it is often about the cheapest way of getting over the 20 or more miles that have to be travelled in the course of the day in order that he may see all his patients."

Under these circumstances it will readily be understood that the interest of the club medical officer is to get as many subscribers on his list as possible. On the other hand, to make the system pay he must give the patients the cheapest possible medicine, he must treat them roughly, so as to discourage their coming too often, and he must despatch each case with the greatest speed. Such economic conditions must tend to degrade the medical profession. Supposing every club medical officer to be a self-sacrificing saint ready to starve himself for the benefit of others, would it be right even for a saint to toil in such a manner for those who can afford to pay the usual fees? At Leicester it was computed that 75 per cent. of the entire population escaped the necessity of paying medical fees when ill. Three-quarters of the population are in receipt of pure charity or poor relief, or belong to clubs, friendly societies, &c. The minimum fee in private practice has not been fixed in an official manner, but nevertheless it may be set down at 1*s.* 6*d.* per consultation given at the practitioner's surgery and 2*s.* 6*d.* for every visit paid at the patient's house In both cases this includes the medicine which the medical practitioner himself dispenses and supplies. It should be clearly established and acknowledged that any one who pays less than this minimum is in receipt of charity. Will it be maintained that three-quarters of the population of Leicester are worthy subjects for charity? On the other hand, if half or two-thirds of these persons paid at least the minimum fee it will readily be seen that the medical practitioners could then afford to give proper attention and good, even expensive, medicines to the remainder. To attain this end a wage limit must be strictly enforced—and such a measure is urgently needed in the interests of humanity and of science. It is difficult to blame a medical officer who neglects club patients when he knows that all the time he is being defrauded and exploited. At one large town I came across a club medical officer who contrived to see 60 patients in the course of an hour. He posted his wife, watch in hand, outside the surgery door. At the expiration of a minute she knocked at the door to make the patient hurry away. Is this not a degradation of science? Is this rush and hurry in the true interests of humanity? And yet, at 2*d.* or so a consultation, what more can the patients expect? If, however, half of these patients paid 1*s.* 6*d.* a consultation then the average income of the medical officer would have sufficed to enable him to give to the other half equally careful and full attention. Thus the claims of humanity would have been better satisfied; on the other hand, and from the point of view of the advancement of science, the medical officer could carefully study his cases and thus extend his knowledge.

Against such a course there is one argument. It may be urged that many artisans, small tradesmen, shop assistants, &c., can very well pay 2*s.* 6*d.* fees for ordinary illnesses of short duration, but not for more serious cases where constant and prolonged medical attendance is necessary. Undoubtedly this is so, but the hospitals are available for many of these more serious cases and there is no objection to a system of insurance which does not employ and exploit medical practitioners A large section of the population are already insured against sickness and receive a sick allowance. It is only necessary to increase this insurance so that it may provide, not only a sick allowance for the maintenance of the patient, but a further sum so that he may be able to pay at least the minimum medical fee and thus be free to choose the medical attendant whom he may prefer. The law of competition would ensure for the patient the best possible medical attendance, for every practitioner naturally strives to preserve his paying patients. With the club system the position is just the reverse, for it best pays the medical officer to give his patients the least possible attention.

---

[1] THE LANCET, April 25th, 1896, p 1163.

THE LANCET, Sept. 21st (p. 757) and 28th (p. 814), 1895.

Again, it must be repeated that club practice institutes economic conditions that tend to the degradation of the profession. Therefore, it can only be tolerated as a charity, and, like many other charities, it will continue to be abused unless a strict wage-limit can be established and maintained.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### *Oxygen and Hydrogen.*

AT the last meeting of the Manchester Literary and Philosophical Society Professor H. B. Dixon stated that Mr. H. Brereton Baker had succeeded in making a mixture of oxygen and hydrogen so pure that it would not explode when the vessel containing it was raised to a red heat or when a silver wire was melted in it. In one case some water was gradually formed, so that the explosion of the gases would seem to depend on the presence of some impurity other than steam itself.

### *The Owens College Associates.*

At a recent meeting of the Associates of Owens College Mr. William Thorburn, F.R.C.S. Eng., was re-elected a governor of the college. Their annual general meeting was held on Dec. 18th, 1901. That the Associates are not devoid of ambition is shown by the passing of the following resolution:—

> That in the opinion of this meeting steps should now be taken to secure that there should be, as originally proposed by the Owens College, an independent university in Manchester.

A resolution was also passed—

> That in the opinion of the Associates the governors of the college should include women.

### *The late Henry Browne, M.D. Lond., M.R.C.S. Eng.*

By the death of Dr. Henry Browne Manchester has lost one of her oldest physicians He died at his residence in Victoria Park on Dec. 28th, 1901, a few weeks before he had completed his eighty-fourth year. For many years he was one of the physicians to the Manchester Royal Infirmary and prior to this he was a member of the honorary staff of the Chorlton Dispensary. The last appointment he held was that of honorary physician to the Mauldeth Hospital for Incurables, an institution in which he took much interest. Though a man of much culture and wide reading he was not a voluminous writer, but he published a volume many years since, "On the Laws of Health and their Correspondence with Revealed Truth." He also wrote a paper on "Oral, Gastric, and Duodenal Dyspepsia," and one on "Positive Nosology" that appeared in the *British Medical Journal* in 1867. He was a man of deep religious feeling and of unostentatious and refined tastes, and for many years he was well known and respected as a painstaking, conscientious, and well-informed physician, though, as he had for several years retired from the practice of his profession, he belonged rather to the past than to the present generation. As one of the local papers says: "Of a quiet and gentle disposition, Dr. Browne was a worthy example of the old type of family physician, and many of the older generation of Manchester citizens will regard his death as a personal loss." He was always much interested in Biblical literature and, as is probably rare in his profession, was a skilled Hebrew scholar.

### *Macclesfield Infirmary.*

The deadlock at the Macclesfield Infirmary is over. There was a special meeting of the governors on Dec. 23rd, 1901, when it was proposed to give Miss Clarke a month's notice to terminate her engagement, but the motion was lost by six votes to three, two of the governors not voting. One of the speakers, evidently referring to the position taken by the medical staff, said in the course of his speech, "The question was, we conclus[illegible]ing to be governors or were they going to be puppets [illegible]nt and almost hopeless to make such people see that this is authorities struggle for mastery on the part of the staff, but now prac[illegible] those who do not object to the movement in favour of women doctors *per se* feel that the mere fact of sex and the instinct of decency set some limitations to the field that can be occupied by women doctors, that there are certain classes of cases occurring in all general hospitals quite unfit for them to treat. It is not encouraging to see such letters as one that has appeared in the *Manchester Courier*, signed "James P. Rountree, Werneth Vicarage," in which the writer speaks of "the domination and bigotry" of the medical staff, &c. It would seem as if some even of the clergy were smitten with impenetrable blindness. Miss Clarke has, however, relieved the governors from their difficulty by resigning her position. The resignation was accepted and a testimonial fund of £100 will be subscribed by the governors. In response to a letter from Dr. C. Averill with reference to the appointment of Miss Clarke's successor, "it was agreed that the applications should be handed to the honorary medical staff in the ordinary course for them to select three candidates from." It is quite possible to sympathise with Miss Clarke and to congratulate her on her escape from a painful position and at the same time to feel that the thanks of the profession are due to the medical staff for the decided stand that they have maintained.

Dec. 31st, 1901.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

### *The Alfred Hughes Memorial.*

THE permanent usefulness of the splendid collection of anatomical dissections and specimens which was presented some years ago to University College, Cardiff, by the late Professor Alfred Hughes is now assured. Mrs. Hughes has, as mentioned last week, added £1000 to the £800 subscribed by Professor Hughes's friends for the endowment of the museum, which is to be called the "Alfred Hughes Anatomical Museum." A memorial medal is also to be awarded in June of each year in the anatomy class of the College.

### *Glamorganshire Asylum.*

An additional block to accommodate 100 female patients is to be erected at a cost of £5000 in connexion with the Glamorganshire County Asylum at Bridgend. At present patients are received from all parts of the county, including Cardiff and Swansea, an arrangement which will cease in March, 1904, when it is anticipated that the new asylum about to be erected by the Cardiff Corporation will be completed.

### *River Pollution*

The Glamorgan County Council has appointed an inspector at a salary of £90 per annum to assist the medical officer of health (Dr. William Williams). His principal duties will be to take samples of water and to collect evidence as to the pollution of streams and rivers. Hitherto the council has not been conspicuously successful in dealing with river pollution within the county.

### *Aberystwith Workhouse.*

Mr. G. R. E. Bonsall, the medical officer of the Aberystwith workhouse, reported to the board of guardians on Dec. 1st, 1901, upon the absence of proper receiving wards and upon the defective ventilation in the sick wards and dormitories and stated that an improvement in the condition of the house would tend to prolong the lives of the inmates The board has, therefore, decided to erect a new workhouse and to sell the existing buildings which are situated about a mile from the town.

### *Navvies' Huts as Common Lodging-houses.*

The lack of a precise definition of a common lodging-house has frequently led to the withdrawal from supervision of many buildings which for all practical purposes are identical with those lodging houses which are registered and regularly inspected. The men employed in the works connected with the restoring of the Thames and Severn canal are housed in huts erected within the area of the Cirencester Rural District Council and the medical officer of health (Dr. Francis Bond) is of opinion that these huts should be registered as common lodging-houses subject to by-laws and to the common lodging-house sections of the Public Health Act, 1875. The district council, however, refuses to accept this view and has merely asked the contractors to give an undertaking that the huts shall be pulled down upon the completion of the works and that the inspector of nuisances shall have power to visit them at any time. The Cirencester District Council can hardly realise what this neglect of a statutory obligation may mean. It is now generally recognised that one of the most common methods of spread of infectious diseases, and especially of small-pox, is through the wanderings of navvies and of other persons who tramp from one town to another, so that if there is one particular class whose surroundings should be carefully looked after it is surely such as these very men who in the Cirencester district are to be allowed to perpetrate—from a public health point of view—any mischief they choose.

### *Winsley Sanatorium for Consumptives.*

The Bath City Council recently determined, if it were legal, to make a grant to the proposed Sanatorium for phthisical patients at Winsley, near Bath. The Sanitary Committee has taken counsel's opinion upon the subject, and at their meeting held on Dec. 23rd, 1901, it was reported that Mr. Macmorran, K.C., had stated that the proposed agreement could be entered into under Section 131 of the Public Health Act, 1875.

Dec. 30th, 1901.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *University of Glasgow.*

THE annual statistical report of the Glasgow University, prepared in accordance with the requirements of the Universities Act and embracing the period from Oct. 1st, 1900, to Sept. 30th, 1901, has just been issued. The total number of matriculated students during the academic year was 2038, of whom 350 were women. Among the new foundations acknowledgment is made of the institution of the Joseph Coats scholarship in memory of the late professor of pathology, also of a grant of £200 from the Bellahouston Trustees for the purchase of apparatus in connexion with the chair of materia medica. It is further intimated that, subject to certain life-rents a residue estate amounting to some £10,000 has been bequeathed to the University for the endowment of a chair in a subject to be determined by the trustees under the will. The report enumerates books added to the library during the year which have reached a total of 2642 volumes. It also gives the salaries of the various professors. In the medical faculty these range from £1645 paid to the professor of anatomy to £215 which is the remuneration received by the professor of clinical surgery.—At a recent University Club dinner Professor John Cleland, in replying to one of the toasts, made an energetic speech, in which he justified the scientific teaching of anatomy, and urged that the subject taught on these lines was not only a mental discipline suitable for inclusion within a university curriculum but that it was the necessary basis for practical medicine and surgery. If anatomy was to be presented on purely utilitarian lines it might be left to the Colleges of Physicians and Surgeons, but studied in a broader light it became an instrument of mental culture and pursued for its own sake it brought a reward in the shape of increased insight and breadth of view. It was the duty of a university, he urged, to teach everything and to maintain the highest standard both in aim and method. Speaking of embryology, Professor Cleland said that the experimental study of this subject was a standing refutation of materialism, and that anatomy was the true foundation of natural theology. Even monstrosities, properly regarded, were manifestations of the beauties of nature, and he hoped that it would soon be the custom for every family to have its own anatomical museum.—It is announced that Professor J. G. McKendrick, who is at present at his residence in Stonehaven, is suffering from an attack of erysipelas which will prevent him for a time from returning to his academic duties.

### *Proposed Small-pox Hospital in Glasgow.*

The Glasgow Corporation have approved of the proposal to erect two pavilions for small-pox patients on the Letham Hill site. In the meantime the opposition to the scheme by the Lanarkshire County Council continues, and the question will require the attention of the Local Government Board of Scotland. The opposition of the council is based upon the proximity of the proposed hospital to inhabited houses and to the fact that the site is close to a large reservoir from which water is supplied to a considerable residential district.

### *Anderson's College Medical School, Glasgow.*

The fifty-fourth annual dinner of the students of this school was held on Dec. 20th, 1901, under the presidency of Professor R. S. Thomson. The attendance was a large one, and included, in addition to the teaching staff, representatives of the University and the other extra-mural schools. In the course of the evening it was stated that there had been a considerable increase in the first-year students and that the college generally was in a flourishing condition.

### *Local Scientific Societies, Glasgow.*

At a recent meeting of the Microscopical Society of Glasgow the President, Dr. Rankin, gave a demonstration of the processes of preparing objects and tissues for examination with the microscope. He also described the several methods of using staining agents and showed a Cambridge rocking microtome with improvements devised by himself. The demonstration was greatly appreciated, and Dr. Rankin was awarded a hearty vote of thanks.—The following have been elected to the honorary membership of the Glasgow Natural History Society: Professor Cleland, F.R.S., Dr. Samuel Chisholm, Professor J. W. H. Trail, F.R.S. (Aberdeen), and Mrs. David Robertson.

### *Western Infirmary, Glasgow.*

The usual Christmas entertainment for nurses and patients was held in this infirmary on Dec. 26th, 1901. A large number of gifts were distributed in the various wards, and addresses were delivered by the Lord Provost and Councillor J. H. Dickson, chairman of the directors. It was stated that every bed in the hospital was occupied and that no fewer than 300 patients were awaiting admission.

Dec. 31st, 1901.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *National Association for the Prevention of Tuberculosis: Dublin Branch.*

AT the last meeting of the Executive Committee held at the Royal College of Physicians of Ireland, Sir John W. Moore being in the chair, special attention was given to the statements in reference to tuberculosis contained in the report of the Registrar-General for Ireland for 1900. From these it appeared that among diseases tuberculosis stood highest as a cause of mortality and claimed 12,848 victims during the year. 10,076 deaths were due to pulmonary tuberculosis, 1026 to tabes mesenterica, and 997 to other forms. The total deaths from tuberculosis represented a rate of 2·88 per 1000, being 0·03 per 1000 in excess of the previous year. The rate from pulmonary tuberculosis was 2·26 per 1000 living. The phthisical death-rates in the four provinces were: Leinster, 2·50; Munster, 2·32; Ulster, 2·24; and Connaught, 1·62 per 1000. The increase of tuberculosis in Ireland was shown by the following returns:—

| | Rate per 1000 of estimated population. |
|---|---|
| Average for 10 years, 1871-80 .. . | 2·6 |
| Average for 10 years 1881-90 .. . | 2·7 |
| Average for 9 years, 1891-99 ... ... | 2·8 |
| Average for 29 years, 1871-99 .. .. | 2·7 |
| Average for 1900 . ... .. ... | 2·9 |

The above figures showed that the mortality from tuberculosis in Ireland was not decreasing, as had been stated, but was gradually increasing. The want of any accommodation, practically speaking, for cases of advanced consumption other than the workhouse infirmaries accounted for the following results in the unions. In the North Dublin Union the death-rate from tuberculosis during the year 1900 was 5·7 per 1000; in the South Dublin Union it was 5·5; in Belfast, 4·4; in Londonderry, 2·9; in Waterford, 3·6; and in Limerick, 3·4.

### *The Royal College of Surgeons and the Royal College of Physicians, Dublin.*

At the present time negotiations are proceeding in a semi-private way in reference to the question of extending the examinations of the Royal College of Surgeons in Ireland and of the Royal College of Physicians of Ireland. For a long time it has been felt to be anything but creditable to Ireland that so many medical practitioners, chiefly educated in that country, take their medical qualifications elsewhere, and these for all practical purposes may be regarded as Irishmen. In his evidence at the recent Royal Commission on University Education in Ireland Dr. W. A. McKeown, basing his statistics on the Medical Directory for 1900, showed that there were 477 medical practitioners in Ireland (the total number in that country is 2575) who had taken their qualifications outside that country, and of these the great majority—370—were diplomates of the Scotch Licensing Bodies. The attractiveness of these Scotch diplomas is twofold—they are cheap and they are easier than most other portals by which students enter the medical profession. The fact is that candidates who fail at the Royal University of Ireland or who never aim at its high degrees, and those who cannot afford the expense at Trinity College, Dublin, wander from all parts of Ireland to Scotland in search of the triple qualification, and an Irish medical teacher constantly finds that the weak members of his class leave finally for "the land o' cakes" to get medically qualified. It is with an idea of stopping this exodus that a move is now being made by the Irish Colleges (of Physicians and Surgeons) to get some of the provincial schools to join with them in providing an Irish portal for those medical students to enter the profession. If this new scheme is to be successful two things are absolutely necessary. There will have to be final examinations in the provinces as well as in Dublin, conducted either simultaneously or alternately, and in each subject of the examinations there will have to be a provincial examiner for every one from Dublin. In no other way will there be any chance of success for this new venture. Many thoughtful members of the medical profession deplore the fact that, apart from all the colleges and universities, there is not in the British Empire, as there is in Germany, a State examination which every student should be compelled to pass before being allowed to enter on practice.

### *Londonderry Asylum.*

At the monthly meeting of the committee of management of this asylum held on Dec. 20th, 1901, the resident medical superintendent reported that an outbreak of typhoid fever had occurred on the female side of the institution, affecting two patients and one female attendant. There were also many cases of sickness and sore-throat. 16 attendants had been more or less off duty from sickness during the month. The place is overcrowded, and the inspectors of lunatics have threatened to recommend the Lord Lieutenant to withdraw the capitation grant if the committee does not proceed without delay to provide accommodation for the inmates of the asylum. It was decided to adopt the plans submitted for the proposed extension at Gransha and tenders for building are to be sought.

### *Death of Mr. Robert Cromie, C.M. Glasg., J.P.*

One of the very oldest medical practitioners in Ulster, Mr. Robert Cromie, J P., died at his residence, at Clough, county Down, on Dec. 18th, 1901. Born in the neighbourhood of Rathfriland, Mr. Cromie studied at Glasgow, where in 1834 he took the degree of Master in Surgery. Returning home he settled at Clough, county Down, where he was dispensary medical officer and where he enjoyed an unusually extensive practice for a lengthened period. No man was better known in county Down (the Yorkshire of Ireland) than was Mr. Cromie, where he was a justice of the peace. A man of great ability, of striking individuality, and with marked gifts, he was very popular with all classes of the community. Mr. Cromie was buried on Dec 21st, a great number of his friends and former patients attending to show a last token of respect to one who had been so kind to them on many an emergency.

### *Banbridge Workhouse.*

Dr. W. Chancellor has been appointed medical officer to the Workhouse Infirmary, Banbridge, county Down, in place of Dr. Waddell (resigned).

Dec. 31st, 1901.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *Death of Dr. Gougenheim.*

THE death of Dr. Gougenheim, who had recently retired, is announced. He was one of the few medical men in Paris who had taken up laryngology and rhinology as a speciality. His department at the Lariboisière Hospital, to which institution he was physician, was often thronged with patients and learners, for it was the only hospital clinic in Paris where the diseases of the throat and nose could be studied. Dr. Gougenheim was a Chevalier of the Legion of Honour.

### *Statistics of the Population of France for 1900.*

The official report upon the population of France for 1900 shows that the excess of deaths over births was 25,988, whereas in 1899 the births exceeded the deaths by 31,394 The result for 1900 is due to two causes. Firstly, there were fewer births—namely, 827,297 in 1900, as against 847,627 in 1899—and secondly to an increase in the number of deaths—namely, 853,285 in 1900, as against 816,233 in 1899. Thus for the year 1900 there were 20,330 births fewer and 37,052 deaths more than in 1899. The death-rate per cent. of the population for 1900 was 2·21, an increase over the mean for the decennium 1890–1899, when it was only 2·16 per cent.

### *A Potato Hydrocarbon Diet in Diabetes.*

Dr. Dujardin-Beaumetz recently put forward the theory that of all starchy bodies potato is that which may be taken by diabetic persons with the least inconvenience. Although this theory has not been universally received, yet M. Mossé, professor at the Faculty of Toulouse, discussed the point before the Academy of Medicine at the meeting held on Dec. 10th. In his opinion potato is not merely slightly harmful but actually beneficial and constitutes an essential element in the treatment of diabetes. M. Mossé gives potato in the place of the ordinary ration of bread in the proportion of three times the weight of potato—i.e., from 500 grammes to two kilogrammes per diem. Far from increasing the sugar the use of potato diminishes its output and chemical examination of the urine shows that the carbohydrates of the potato are absorbed and utilised. The results are better in that form of diabetes which is marked by thinness than in the fat form. The *rationale* of the treatment is probably that potato contains twice the amount of water weight for weight that bread does and nearly the same quantity of potassium salts Therefore if a patient takes a weight of potato three times greater than his ordinary quantity of bread he takes six times as much water and three times as much potassium salts, while the quantity of albuminous and starchy matter remains practically unchanged. Potassium salts are an integral part of the alkaline treatment of diabetes and the good which they do easily counterbalances the harm done by the ingestion of the starchy matter. Under the potato treatment the sugar disappears, the general health improves, as does also the appetite, and if the patient is not cured he at all events lives under quite supportable conditions. M. Mossé's results will have great interest for sufferers from diabetes, as potatoes are within the reach of everybody's purse.

### *The Prophylaxis of Venereal Diseases.*

In consequence of the excitement caused by the prohibition of the new play *Les Avariés*, which I have mentioned in a previous communication,[1] and owing to the foundation of a society for the furtherance of both hygienic and moral prophylaxis, the Minister of the Interior has just appointed a commission. This commission is to be charged to inquire into the various questions connected with syphilis and other venereal diseases, especially their prophylaxis. It will also inquire into the frequency of these diseases, into the condition and management of the various institutions existing in France for their treatment, and into the best means, both legislative and administrative, for preventing the spread of such complaints.

Dec. 31st, 1901.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *Statistics of the Medical Profession in Germany.*

ACCORDING to Hirschwald's Medical Directory, edited by Dr. Wehmer and quoted in the *Vossische Zeitung*, there are now 27,039 medical men in Germany, an increase of 560 over the number for 1900, which was 26,479. Since 1897 the increase of the profession is 2646 = 10·7 per cent. ; that of the population in general is 6·1 per cent. 16,500 medical men reside in Prussia, 2724 in Bavaria, 1967 in Saxony, 1019 in Baden, 1009 in Wurtemberg, 766 in Alsace-Lorraine, and the remainder in the smaller States of the Empire. In Berlin there are 2305 medical men residing, and it is interesting to note that the increase of the profession in the metropolis is rather less than in last year, being 43 = 1·9 per cent. only. Munich has 654 medical men, Hamburg 569, Breslau

---

[1] THE LANCET, Nov. 16th, 1901, p. 1357.

520, Dresden 428, Leipsic 418, Cologne 346, Charlottenburg 336, and Frankfort 331. In the larger towns a decrease *in the number of medical men occurred only in Bremen.* As to the age of the Berlin medical men there is one practitioner who qualified in 1842, while 18 others qualified more than 50 years ago. The latter class includes Professor Virchow, who qualified as early as in 1846. Of Berlin practitioners 40 qualified 49 years ago, 166 from 30 to 39 years ago, 278 from 20 to 29 years ago, 753 from 10 to 19 years ago, and 853 within the last 10 years. To every 10,000 of the population there are on an average 4·80 medical men, this number varying from 7·55 in Hamburg to 2·63 in Reuss. In Berlin there are 12·22 medical men for each 10,000 of the population. The number of dentists continues to increase from year to year. There were 1586 in 1901, 1489 in 1900, 1401 in 1899, 1327 in 1898, and 1238 in 1897. Of licensed pharmacies there are 5559, this number having increased by 100 as compared with that of the preceding year. In Berlin there are 167 pharmacies. For each 10,000 of the population there are 0·99 pharmacies.

### *Researches on Cancer.*

A citizen of Frankfort has recently bequeathed to the municipal authorities of this town the sum of 500,000 marks, equal to £25,000, of which the interest is to be expended on researches concerning the etiology of carcinoma. The city of Frankfort has handed over these funds to Professor Ehrlich, the celebrated bacteriologist who is at the head of the institution of experimental therapy there. Apart from this legacy Professor Ehrlich has at his disposal other considerable funds for this purpose. In Berlin, as has been already reported in these columns, a committee exist for collective investigations on cancer. Professor Czerny, who is one of the committee, has recently issued a circular letter to all the surgeons of Germany asking them to state after what lapse of time on an average recurrence is wont to occur after the operation for cancer of the mamma. In this way the committee hope to get sufficient material to ascertain the duration of the latent period of the disease.

Dec. 23th, 1901.

## Obituary.

### JAMES JOSEPH TRACY, M.B., M.CH., B.A.O. R.U.I.

CORK has lost a well-known member of the medical profession by the death of Dr. J. J. Tracy on Dec. 26th, 1901. He was educated at the Queen's College, Cork, and graduated at the Royal University of Ireland in 1890. For a brief period he became an assistant in England, but returned to Cork, his native city, and was appointed surgeon to the Mercy Hospital. Subsequently he transferred his services to the medical side of that institution and was appointed physician. He took a great interest in the Cork Medical and Surgical Society, of which he was honorary treasurer, and his remarks in debates were listened to with much attention. He took a very active part in "the battle of the clubs" at Cork, and in the early days of the fight he was appointed one of the honorary secretaries of the medical organisation. When it was decided to draw up a code of rules to bind the local profession together Dr. Tracy displayed a wonderful prescience of the difficulties which were likely to occur and by his foresight considerably helped his profession. As the fight went on it was seen that it would be necessary to offer an alternative to men in humble circumstances who desired to become members of a club and it was decided to establish the Cork Medical Benefit Society. Dr. Tracy at once mastered the intricacies of the Friendly Societies Act, and mainly under his guidance rules were drawn up which readily obtained the sanction of the Registrar of Friendly Societies, and the Cork Medical Benefit Society became an established fact. Its membership is steadily increasing, and from every point of view it is a distinct success.

Last winter, acting on the advice of his medical friends, he decided to make a sojourn in the south of France for the benefit of his health. On his return it was seen that he was suffering from tuberculosis in an advanced stage, but with characteristic energy he worked on to the last. A week before he died he was visiting his patients. His funeral was most representative, his medical brethren attending in large numbers, the lord mayor and the high sheriff of the city being also present.

## Medical News.

UNIVERSITY OF LONDON.—At the B.S. examination for honours the following candidates were successful:—

*Surgery.*—First Class: Felix Bolton Carter, M.D., University College; Arthur Edmunds (Scholarship and Gold Medal), King's College; and Thomas Copeland Savage (Gold Medal), University College. Second Class: Charles Archibald Scott Ridout, St. Bartholomew's Hospital; and Ralph Paul Williams and W. Halliburton McMullen, King's College. Third Class: Ernest Lewis Lilley, Charing Cross Hospital.

N.B.—The foregoing list, published for the convenience of candidates, is provisional only, and is not final until the reports of the examiners shall have been confirmed by the Senate.

DONATIONS AND BEQUESTS.—A donation from "H. M. E." of £500 has been received by the Chelsea Hospital for Women.

MEDICAL MAGISTRATE.—The Lord Chancellor has placed Dr Henry John Mackay on the commission of the peace for the borough of Devizes.

EPSOM COLLEGE.—Mr. A. J. May of Epsom *College has been elected to an open scholarship for Natural* Science of the value of £50 at Sidney Sussex College, Cambridge.

A MEDICAL PEER.—Herr Coloman Müller, professor of medicine at the University of Hungary, chief physician of the Rochus Hospital, and organising secretary of the eighth Congress of Hygiene and Demography held at Budapest in 1894, has been elevated to the House of Magnates of Hungary.

VACCINATION PROSECUTIONS. — At the Truro Police-court on Dec 23rd, *1901*, several persons were summoned for neglecting to have their children vaccinated. Orders were made for the vaccination of the children within 14 days and for the immediate payment of 10s costs, with distress or imprisonment in case of non-compliance.

BOARDS OF GUARDIANS AND ISOLATION HOSPITALS.—At the meeting of the Yeovil Board of Guardians held on Dec. 20th, 1901, a communication was received from the town council inviting the guardians to coöperate with the council in the enlargement of the isolation hospital. After a prolonged discussion the guardians decided that the duty of providing an isolation hospital for Yeovil, including paupers, whether inmates of the workhouse or not, rested with the town council as the sanitary authority of the district, and that the guardians were under no obligation to contribute towards the cost of such hospital further than by payment of the expenses of such paupers as might from time to time be in the hospital.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—At Abercarn, Monmouthshire, on Dec 14th, at a public meeting, Mr. Edmond Walsh, L.R.C.P. & S. Edin., L.F.P.S. Glasg., was presented *with an illuminated address*, a gold watch suitably inscribed, and a gold chain as a mark of respect and esteem on the occasion of his leaving the neighbourhood.—Mr. William Parson, M.R.C.S. Eng., M. & L.S.A., J.P., medical officer of health of Godalming, on his retirement from private practice was recently presented by his old patients and friends with a silver tea and coffee service in Louis XIV style, a pierced silver cake basket, a tea urn, a tray, a silver lamp with column and base and Corinthian capital, and a Chippendale easy chair.

CONSUMPTION SANATORIUM IN WORCESTERSHIRE.—Earl Beauchamp is actively interesting himself in the movement for erecting an open-air sanatorium for the reception of consumptive patients in Worcestershire. His lordship has sent a cheque to the honorary treasurer (Dr. H. E. Dixey) of Woodgate, Malvern. Mr. George Cadbury has warmly endorsed the scheme and has given a donation of £100, with a promise of £200 annually towards maintenance. Mr. Alfred Baldwin, M.P., has sent £100, and a like sum has been received from Mrs. Williams, a former resident of Malvern; Mr. H. Howard, chairman of the Sanitary Committee of the county council, has given £50; Mr. James Atkins, £52 10*s.*, and *Dr. Dixey*, £50. The estimated cost of a sanatorium with 48 beds is £12,500, but the committee intend to start in a small way by spending £5000 on sufficient accommodation for 20 beds. Committees are being formed all over the county for the purpose of obtaining subscriptions, and the committee are hopeful of starting building operations in about three months' time.

CARDIFF AND COUNTY PUBLIC HEALTH LABORATORY.—The Cardiff and County Public Health Laboratory was established in the first instance in the year 1898 by the Glamorganshire County Council who spent about £500 in the erection of a suitable building and upon apparatus, &c. In June, 1899, the laboratory came under the joint control of the county borough of Cardiff and of the Glamorgan County Council, when the administration was placed in the hands of Dr. E. Walford (medical officer of health of Cardiff) and Dr. W. Williams (medical officer of health of Glamorganshire). The paid staff consists of a clerk to the joint committee, a bacteriologist (Dr. W. G. Savage), an assistant bacteriologist, and an attendant. The expenditure incurred by the committee from June, 1899, to the end of March, 1900, was £436, and for the year ending March 31st, 1901, it was £743. In the last report of the directors they state that during the three months ending Nov. 30th last 51 samples of water were submitted to chemical analysis and 77 to bacteriological examination; 178 specimens were examined bacteriologically—64 being for diphtheria bacilli and 60 for tubercle bacilli—and 31 specimens were submitted to pathological or chemical examination. Five medical practitioners are attending the public health lectures and are receiving practical laboratory instruction, while the classes for sanitary inspectors are being attended by 22 students.

## BOOKS, ETC., RECEIVED.

BRITISH MUSEUM (NATURAL HISTORY), Trustees of, Cromwell-road, S.W.

A Monograph of the Culicidæ or Mosquitoes. Mainly compiled from the collections received at the British Museum from various parts of the world in connexion with the investigation into the Cause of Malaria conducted by the Colonial Office and the Royal Society. By Fred. V. Theobald, M.A., F.E.S. Two volumes and book of plates. Printed by order of the Trustees. Price not stated.

CHATTO AND WINDUS, 111, St. Martin's-lane, W.C.

Herbert Fry's Royal Guide to the London Charities. Edited by John Lane. Thirty-eighth Annual Edition. Price 1*s.* 6*d.*

FISCHER, GUSTAV, Jena.

Die Bakterien. Naturhistorische Grundlage fur das Bakteriologische Studium. By Johs Schmidt and Fr. Weis. With a Preface by Professor Dr. E. Chr. Hansen, Carlsberg Laboratorium, Copenhagen. Price 7 marks.

WARD, LOCK, AND CO., Limited, London, New York, and Melbourne.

Underground Watering of Plants and Gardens, to which is added hapters on the Culture and Propagation of Rose Trees. By John Grant. Price 1*s.*

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BARBER, A., L.R.C.S.I., has been appointed Government Medical Officer and Vaccinator at Penrith, New South Wales.

BODY, HENRY MARTEN, M.R.C.S., L.S.A., has been appointed Medical Officer for the Sandford District of the Crediton (Devon) Union.

BOON, J. G., L.R.C.P.I., L.R.C.S.I., has been appointed Certifying Surgeon under the Factory Acts for the Borough of Wenlock in the county of Salop.

CREED, Hon., J. M., M.R.C.S., M.L.C., has been appointed Chairman of the Visiting Committee for Institutions licensed under the Inebriates Act, 1900, New South Wales.

DAKIN, T. B., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Acts for the Ulceby District of Lincolnshire.

DEANE, E. W., M.B. Melb., has been appointed Officer of Health for the Borough of Carisbrook, Victoria.

DOUDNEY, E., M.R.C.S., has been appointed Government Medical Officer and Vaccinator at Port Macquarie, New South Wales.

FENWICK, CHARLES, L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Cheriton Bishop District, Crediton Union.

FETHERSTON, R. H. J., M.D. Edin., has been appointed Officer of Healt for the city of Prahran, Victoria, and Certifying Medical Pract tioner under Factories and Shops Acts, Metropolitan District Melbourne.

GOADBY, KENNETH W., L.D.S. Eng., D.P.H. Camb., has been appoint Bacteriologist and Lecturer on Bacteriology to the National Dent Hospital.

GRAHAM, A. W., M.B. Lond., has been appointed Medical Officer Health for the District of Beaconsfield and Dalrymple, Tasmania.

GREEN, FREDERICK KING, F.R.C.S. Eng., L.S.A., has been appoint Honorary Consulting Surgeon to the Royal United Hospital, Bat

HALL, J. N., M.R.C.S., L.R.C.P. Lond., has been appointed Medic Officer of the Mayfield District of the Uckfield Union.

HAYCROFT, CHARLES H., M.R.C.S., L.S.A., has been re-appoint Medical Officer for the Coleridge and Colebrooke Districts of t Crediton Union.

JEROME, ERNEST J., L.R.C.P. & L.R.C.S. Edin., has been re-appoint Medical Officer of Health for the Camelford (Cornwall) District.

KNOTT, E. M., M.R.C.S., L.R.C.P. Lond., has been appointed Medic Officer of Health for the Brixworth Rural District.

LACK, H. LAMBERT, M.D. Lond., F.R.C.S., has been appointed Au Surgeon to the London Hospital.

LONERGAN, T. J., L. & L.M.R.C.P. & R.C.S. Edin., has been appointed District Medical Officer and Public Vaccinator, Northampton, Western Australia.

M'KENDRICK, G. BROWNLIE, F.R.C.P., F.R.C.S. Edin., L.F.P.S. Glasg., has been appointed to take charge of the Department for Kidney and Urinary Diseases in the Glasgow Public Dispensary

MANLY, R. A. A., M.B. Melb., has been appointed Medical Officer of Health for the Shire of Lancefield, Victoria.

MUIR, W. C. C., M.B. Glasg., has been appointed Officer of Health for the Shire of Alberton, Victoria.

O'BRIEN, J. A., M.B. Glasg., has been appointed a Member of the Medical Board of Victoria.

O'FLAHERTY, L. S., L.R.C.P. Edin., has been appointed Public Vaccinator at Bulong, Western Australia.

PARDOE, JOHN, M.B., M.R.C.S., has been appointed Surgical Assistant to St. Peter's Hospital, Covent-garden.

POWNE, LESLIE, M.R.C.S., L.S.A., has been re-appointed Medica Officer for the Newton St. Cyres and Shobrooke Districts of t Crediton Union.

RIDOUT, C. A. S., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has bee appointed House Surgeon to the North Staffordshire General Infi mary and Eye Hospital, Stoke-on-Trent.

ROWAN, T., L. & L.M.R.C.P. & R.C.S. Edin., has been appointe President of the Medical Board of Victoria.

SCOTT, A. T., M.B. Glasg., has been appointed Public Vaccinator f Whangaroa, New Zealand.

SCOTT, RICHARD JAMES HERBERT, F.R.C.S. Edin., has been appointe Honorary Consulting Surgeon to the Royal United Hospital, Bath.

SMITH, G. U., M.B. Lond., has been appointed Bacteriologist to th Cambridge Town Council.

SPRINGTHORPE, J. W., M.D. Melb., has been appointed Visitor to t Metropolitan Lunatic Asylums, Melbourne, Victoria.

STENHOUSE, A., M.A., M.B., B.Ch. Univ. N. Z., has been appointe Public Vaccinator for Blackstone, New Zealand.

STEVENS, THOMAS GEORGE, M.D. Lond., F.R.C.S. Eng., M.R.C.P. Lond has been appointed Obstetric Tutor to St. Mary's Hospital.

STEWART, J. E. F., M.B. Glasg., has been appointed Officer of Healt to Bayswater Local Board of Health, Western Australia.

TEAGUE, D. G. M., M.B. Edin., has been appointed Public Vaccinato at Kanowna, Western Australia.

TUCKER, JOSEPH, M.R.C.S., L.S.A., has been re-appointed Medica Officer for the Chawley District, Crediton Union.

WADE, CHARLES, L.R.C.P., M.R.C.S., has been re-appointed Medica Officer of Health for the Boscastle (Cornwall) District.

WINTER, W. H. T., M.R.C.S., has been appointed a Medical Refere under the Workmen's Compensation Acts, 1897 and 1900, and to ac for the Wolverhampton County Court District of Circuit No. 25.

## Vacancies.

# Births, Marriages, and Deaths.

## BIRTHS.

**ACKENBURY.**—On Dec. 25th, the wife of Henry B. Brackenbury, M.R.C.S., L.R.C.P. Lond., of a daughter.

**THELL.**—On Dec. 26th, at Merton House, Ross, the wife of Arthur Cuthell, B.A., B.Sc., M.R.C.S., of a son.

**UHIG.**—On Sunday, Dec. 29th, 1901, at Little Langtons, Hornchurch, Essex, the wife of David John Duhig, M.B., L.R.C.P., of a daughter.

**ALKER.**—On Dec. 29th, at Worple-road, Wimbledon, the wife of George Walker, M.R.C.S., L.R.C.P. Lond., of a daughter (Mary Hildegard).

## DEATHS.

**ARRINGTON.**—On Dec. 26th, at 8, Battersea-rise, S.W., aged 45 years, Dr. William Henry Carrington, L.S.A., L.R.C.P. (suddenly), youngest son of the late Mr. Frederic George Carrington, *Gloucestershire Chronicle*, Gloucester.

**EAKE.**—On Dec. 27th, at Orotava, Teneriffe, Matthew William Stuart Leake, M.R.C.S., L.R.C.P. Lond., aged 30.

**ASON.**—On Dec. 29th, at Albany-road, Stroud-green, N., John Wallis Mason, M.R.C.S., L.S.A., in his 80th year.

**HAW.**—On the 31st of December, 1901, at the residence of her parents (Dr. and Mrs. Merson), De-la-Pole, Hull, Amy Gertrude, aged 31, beloved wife of J. Custance Shaw, M.R.C.S., L.R.C.P.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

### MEDICAL PRACTITIONERS AND THE SALE OF POISONS.

*To the Editors of* THE LANCET.

SIRS,—The recent edict of the General Medical Council constitutes it "infamous conduct" for a medical practitioner to leave in charge of a medical hall or shop where scheduled poisons are sold to the public a person not legally qualified to sell these. Now I am at a loss to know whether by the words "sold to the public" is meant only selling the poisons in their simple (unmixed) state or does it apply to dispensing medicines containing them to one's patients, for is not the handing over for money of a poison, mixed or diluted, as much a sale as retailing the unmixed article? And is not one's patient a member of the public? Also, is not the place where such mixtures are sold—be it a "surgery," "dispensary," or whatever it may be called—not a "shop" or "medical hall"? If this view be correct every medical practitioner throughout the kingdom who cannot afford to keep a qualified dispenser must either have no dispensary or surgery containing scheduled poisons or lock it up in his absence, leaving no one, not even a senior student, far less his wife, family, or domestic, in charge of it. How much more has the long-suffering general practitioner to endure at the hands of the General Medical Council?—I am, Sirs, yours faithfully,

Dec. 30th, 1901. VULNERATUS.

### THE DISSEMINATION OF INFECTIOUS DISEASE.

*To the Editors of* THE LANCET.

SIRS,—A poor woman of my acquaintance recently found her youngest child ill and took him to a large hospital in her district. The malady was pronounced to be scarlet fever. The hospital ambulance conveyed the mother and child back to their one-roomed home with three other child occupants in a house of many tenants. The public medical officer of health acted, I believe, as promptly as circumstances permitted and in 24 hours or so the fever-stricken patient was removed. Is it impossible for large general hospitals to have an isolation ward where infectious cases might be detained pending their transference to the care of the Metropolitan Asylums Board? Such a course would seem to possess some advantages to AN OUTSIDER.

Dec. 28th, 1901.

### MEDICAL AID ASSOCIATIONS AND THE GENERAL MEDICAL COUNCIL.

*To the Editors of* THE LANCET.

SIRS,—In answer to your correspondent, Mr. Harry Clough, in THE LANCET of Dec. 28th, 1901, p. 1848, whose wish seems to be to vindicate the medical aid associations and to champion the unqualified assistant, I would like to offer a few remarks. In the first place let it be understood that I write as a general medical practitioner. The first duty of the General Medical Council is to guard the interests of the public and though progress is slow and at times erratic some noteworthy successes have been achieved. It is admitted that the general practitioner is a hard-pressed individual, but whose fault is that if not his own? People judge the practitioner very largely as he estimates himself and if the club doctor values himself at a penny per week he is valued by his patients accordingly. The stringent rule as to unqualified assistants at least prevents men with large club practices from employing these in the same manner as formerly, and makes room for the legitimate article. In other words it prevents the covered competition that we were at one time subject to. The Midwives Bill has not made much progress, so we can turn to the later effort of the General Medical Council, the veto against the medical aid associations—in plain English a veto against clubs in connexion with insurance companies where canvassing is carried on and where the bait offered for insurance is the services of a qualified practitioner. I assert, and I think every man with any claim to common sense will give me his support, that professional knowledge cannot be increased by contract work, and to compare it with the training and experience to be obtained at a general hospital is, to say the least, ridiculous. The time at one's disposal is much too short to make a satisfactory examination of the case, let alone to take that thorough interest which is essential to obtain good results. Advertisement is granted, but is it fair to allow one's name to be touted from door to door and one's services held out as an inducement to insure? Does it give true merit the best chance and reward those deserving of reward? I know from experience that the beginner would have a better chance if he took no medical aid work, for I know that whatever work fell to his lot would be done well and the healthy interest he would bring to bear on the case would have its own reward. The young practitioner does not shine in the public eye as an officer in a medical aid company. When anything serious comes along he is passed over with "he is only a club doctor," and the man who does no club work is employed. The General Medical Council has conferred a very great benefit on the beginner in holding him aloof from such work. Your correspondent points out that medical aid cases are usually trivial; where then does the experience that he would have as against this mean come in? To my mind, it teaches the impossibility, however earnest the man may be) of attending more than a given number of cases in a manner that will reflect credit on the medical man and the profession. No; contract work is not, and never can be, science. The practitioner is entitled to remuneration for his work and the public is entitled to have the work done in a thorough manner, and not in the slipshod method that club work leads to. Who ever saw a man who adhered to medical aid work rise in his profession? He remains a hack, a common drudge, at the beck and call of every 1*d.* and ½*d.* subscriber to the club, and undertakes an amount of work that it is physically impossible to do properly. 3. I would like to see the General Medical Council go one or two better. I would like to see them prohibit contract work absolutely, make a fixed scale of charges and treat the provident dispensary employing canvassers as they have done the medical aid companies. Then, and not till then, will the beginner have an equal chance. He will then have time to study, which is very necessary, he will be able to show some interest in his work, and the public will reap some benefit. Contract work is humbug and no man with broad views on the standing of the profession would be satisfied with it. When the young practitioner gets a few more years over his head time will have probably demonstrated to him the truth of my remarks. His energy would be well spent in other directions instead of championing what is to a great extent the curse of the profession. Apologising for the amount of space I have occupied,

I am, Sirs, yours faithfully,

Leicester, Dec. 28th, 1901. JOHN MACCORMAC.

## SECOND-HAND.

*To the Editors of* THE LANCET.

SIRS,—Will you let me ask through your columns if any of your readers could make use of an invalid's bed-table and a "Turkish bath at home" which will be disposed of at half their cost, although practically as good as new? The bath, one of the sort known as a "Thermal Cabinet," has only been used once or twice. The bed table is of the ordinary pattern, the heavy foot standing on the ground and the slab turning over the patient's bed and forming a table on which to rest writing materials, a book, or a plate.

I am, Sirs, yours faithfully,

Dec. 30th, 1901. X. Y. Z.

## WEIR MITCHELL TREATMENT.

*To the Editors of* THE LANCET.

SIRS,—Would any of your readers kindly inform me if there is any hospital or institution in London where a servant could have Weir-Mitchell treatment? I am, Sirs, yours faithfully,

Jan. 1st, 1902. PHENAD.

## THE BAEL TREATMENT OF DYSENTERY.

*To the Editors of* THE LANCET.

SIRS,—As fatal cases of dysentery have been rather numerous among our troops in South Africa, I have frequently wondered whether the Indian bael treatment has been adopted for the cure of that terrible disease. The fresh fruit is undoubtedly the finest remedy for dysentery that could be used; it is extensively prescribed by the medical profession in Calcutta with the very best results. It is not so much used in Upper India, where the bael tree does not appear to thrive so well as in the continuously warmer temperature of the lower provinces. Not being a member of the profession I feel some diffidence in venturing to write these few lines to you on the subject, but I do so as I have known the great value of the bael fruit during my residence in India of over 30 years. I was myself cured of an exceedingly severe and prolonged attack of dysentery by that remedy (albeit from dried fruit in pulverised form) after other treatment had signally failed. The same occurred in the case of one of my children who (while absent from me) was believed to be dying at a hill sanatorium. I was sent for by telegram, and thinking that bael would not be there procurable I took up some powdered bael which was prepared in Calcutta, and with the medical man's permission gave some doses of it to the apparently dying child. It was a very difficult job, in his utterly prostrate condition, but the result was that his life was saved. I have known other cases of recovery from dysentery and severe diarrhœa effected by bael, a remedy I always kept in my house in India (I do so still in England), and though I am a layman I have always strongly recommended it for the above very obvious reasons. The tinctures of bael I have not found effective; the fresh fruit, or the powdered, are splendid remedies for dysentery. Bathgate and Co., chemists, of Calcutta, have an excellent preparation of powdered bael which they call "Dietetic Bael." I used this in my own case with perfect success and many others have been grateful to me for telling them of it. In my humble opinion were this preparation to be used freely in South Africa we would not read of many fatal cases of dysentery in the lists of casualties. I write this letter with all due deference to the profession; perhaps you may deem it suitable for insertion in your valuable journal.

I am, Sirs, yours faithfully,

J. E. B. PARSONS, Major-General, I.S.C.

Southbourne, Hants, Dec. 21st, 1901.

⁂ Bael in the treatment of dysentery has long been well known, and it has been, and still is, frequently prescribed in India. Preparations of the fresh fruit should be used, other forms of it being comparatively inert. Squire and Sons of 413, Oxford-street, London, obtain the fresh fruit direct from India which they keep in the form of a confection. As we are occasionally asked about bael we may say th this preparation of it is a good one and it is occasionally found to of use in some of the chronic forms of dysentery met with in the who have contracted the disease abroad and returned to this countr For those desirous of trying this remedy the confection makes palatable and pleasant form in which to prescribe it.—ED. L.

◆

*For 35 Years a Subscriber.*—1. Yes; the statement that "when t income exceeds £160 but does not exceed £400 a year, an abateme of £160 may be claimed," is quite correct. The abatement should claimed each year on the same form as that on which the annu return of income is made—the usual six-page buff form. 2. N repayment cannot be claimed for all the years of overcharge—thr years is the limit. 3. Apply to the Secretary, Inland Reven (Repayment Branch), Somerset House, London, W.C., for the nece sary forms, if it is decided to make a claim for repayment.

*Doubtful.*—The fee would in this case be chargeable to the patient father who called in the medical man and made use of his servic Such fee is usually one guinea, but, if the circumstances of the ma do not permit of his paying it, a lower fee, usually half a guine is often charged. The magistrate may be appealed to if the ma declines to pay and an order for payment can then be secured, to presented to the clerk to the board of guardians in whose jurisdi tion the patient is.

*L.R.C.P.*—We could not possibly act as agents in the matter. O correspondent might write to the Society of Authors, 39, Old Queen street, Storey's-gate, S.W.

*Materfamilias.*—Fifty-one years ago. A new edition has just bee published by Messrs. John Murray, in a paper cover, admirabl printed, price 1*s.*

*X. Y. Z.*—Cold baths are certainly inadvisable in the circumstance described by our correspondent.

*M.I.C.E.*—We do not think that our correspondent's theory will hol water at all.

*Gec.*—The question is purely legal.

COMMUNICATIONS not noticed in our present issue will receive attentio in our next.

# Medical Diary for the ensuing Week.

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY** (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.) St Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M. Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M. **THURSDAY** (9th) —THE HOSPITAL FOR SICK CHILDREN (Gt Ormond street W C ) —4 P M Dr Fennell Pathological Demonstration

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "To THE EDITORS, and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

*It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this Office*

*Lectures, original articles, and reports should be written on one side of the paper only* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

*Letters, whether intended for insertion or for private information must be authenticated by the names and addresses of their writers—not necessarily for publication*

*We cannot prescribe or recommend practitioners*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"*

*Letters relating to the publication sale, and advertising departments of* THE LANCET *should be addressed "To the Manager"*

*We cannot undertake to return MSS not used*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET

THE Index to Vol II of 1901 which was completed with the issue of Dec. 28th and the Title page to the Volume are given in this number of THE LANCET

### VOLUMES AND CASES

VOLUMES for the second half of the year 1901 will be ready shortly Bound in cloth gilt lettered price 18s, carriage extra

Cases for binding the half year's numbers are now ready cloth, gilt lettered, price 2s, by post 2s 3d

To be obtained on application to the Manager, accompanied by remittance

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices

Subscribers by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free either from THE LANCET Offices or from Agents, are —

| FOR THE UNITED KINGDOM | | TO THE COLONIES AND ABROAD | |
|---|---|---|---|
| One Year | £1 12 6 | One Year | £1 14 8 |
| Six Months | 0 16 3 | Six Months | 0 17 4 |
| Three Months | 0 8 2 | Three Months | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "*London and Westminster Bank, Westminster Branch*") should be made payable to the Manager Mr CHARLES GOOD, THE LANCET Offices 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or on any other ground, should be resisted The Proprietors of THE LANCET have for many years paid, and continue to pay the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect and do so collect from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates whatever be the weight of any of the copies so supplied Address—THE MANAGER THE LANCET OFFICES 423 STRAND LONDON, ENGLAND

# A Presidential Address

ON

# SOME DISEASES INCIDENTAL TO SCHOOL LIFE IN NEW ZEALAND, WITH SUGGESTIVE METHODS FOR COMBATING THEM.

*Delivered before the Members of the New Zealand Branch of the British Medical Association at their Annual Meeting at Wanganui.*[1]

BY G. R. SAUNDERS, M.B., B.C. CANTAB., &c.

MR. PAST-PRESIDENT AND GENTLEMEN,—In acknowledging the honour you have done me in electing me as your President a feeling of satisfaction and anxiety is very apparent to me—satisfaction that things have so befallen me that you should consider me worthy to preside over your deliberations, and anxiety that the debt which I owe you in return will, in all probability, be poorly and inadequately repaid. I have chosen for my address a subject that I have long considered ought to be fully ventilated—a subject that concerns all Britishers—a subject which pertains to the gospel of flesh and blood, the gospel that has made England and the gospel that will maintain Greater Britain in the future—viz., attention in every detail to our rising generation.

There is no doubt that the State can soon discipline its men if they are of the right sort, but the problem that lies nearer to us as members of the medical profession is to do all we can to encourage those ideas which we know full well will build up the stamina of the race and which, if carried out, will tend to give the nation healthy men and women fit to play their parts as individuals, as units of a nation, and as the breeders and rearers of the future representatives of Great Britain and her colonies. Herbert Spencer indeed aptly put it when he wrote: "To be a nation of healthy animals is the first condition of national prosperity." The object of my address to-night is not to tell you anything new on the subject, but to endeavour to keep this, to my mind, most important theme ever green before you, and to endeavour in this way, by perseverance, patience, and determination, to bring the subject by degrees—if by no more rapid movement—prominently before the existing authorities until the end has been accomplished. It is only at our annual conferences that such opportunities arise, for, like the stewards of the English Jockey Club, the members of the medical profession do not, as a rule, write to the newspapers airing their thoughts and grievances. The English Jockey Club through their stewards speak out their minds on affairs connected with the Turf from time to time at the annual dinner of the Gimcrack Club which has been held at York for the past 134 years. This is the opportunity embraced by those interested reformers in Turf pursuits to express their thoughts, to make suggestions, and to criticise shortcomings generally. During the past few years marvellous Turf reforms have resulted as a sequel to these expressions, and great benefit in the way of purifying the Turf of many objectionable practices has come about. Now this conference gives us the same opportunity of doing so from a medical standpoint. We are all by the nature of our calling very apt to get into grooves, but in attending gatherings such as this in which we now have the privilege of taking part we are forced out of the groove. We amend views which by necessity tend to become parochial and accordingly regain our power of observation and correct thought. The gain is, therefore, all round to our advantage and to the advantage of our patients. It consequently comes about that the laity look to conferences such as this our annual gathering to speak with an authority such as no individual can exercise on any question which affects the public welfare, and to give such advice and solemn warnings as may assist the real lay reformer to check the evils which we happen to place before him, and especially those which are likely to affect generally the health and development of the nation as a whole and of its rising generation in particular. I feel, therefore, that it is my duty to do something in this direction and I cannot, I think, do better than follow in the wake of some of my immediate predecessors in the presidential chair in choosing as a subject the following: "Some Diseases Incidental to School Life in New Zealand with Suggested Methods for Combating Them." This subject, I feel sure you will all agree with me, is one of great seriousness and includes a vast variety of diseases. My object is to draw your attention to but a few of them—for the time at my disposal is limited—those which in my opinion are of paramount importance.

## THE EYESIGHT OF SCHOOL-CHILDREN.

In the first place, the question of eyesight in schools is one of the highest interest and demands great attention. There can be no possible doubt whatever, it appears to me, that abundant and convincing evidence exists that the vision of school-children, which should apparently under normal conditions have remained sound, is constantly deteriorating during the epoch devoted to school life. Expanded knowledge explains why it comes about that we see so many children and youths walking about with spectacles at the commencement of the twentieth century than was formerly the case. As a matter of fact, the eye in youth is often asked to perform tasks which it cannot possibly accomplish. There was a time when distant vision was the only sight required, that for near objects being trivial in comparison to it; but general civilisation has completely altered this state of things and the existing condition is now exactly the opposite—viz., the eyes are now used almost constantly for near objects and that for distance only occasionally in proportion to the past. The long hours of study that even little children spend over work close to their eyes is the cause which brings us to the opposite extreme. The means by which the eye accomplishes this close work is of course entirely muscular, and when "focussing" is undertaken for a near object convergence of course accompanies it. The growth, development, and the functional activity of the eyes, as of other bodily organs, are influenced by the amount of work which they are called upon to do. The normal or emmetropic eye is so constructed as to obtain perfect distant vision of objects not less than 20 feet away. There is, then, no individual adjustment, and therefore it is in a passive condition as regards its fellow. As this distance is diminished the eyes assume in a constantly increasing ratio an altered shape and direction, and this can only be accomplished by muscular effort obtained by increasing the convexity of the internal lens. The result is that weariness will ensue just in the same way as an overtaxed biceps becomes weary.

*It will not be difficult to show that the process of ordinary* scholastic education, as applied to the young, or the circumstances associated with higher civilisation, tend to the production and promote the handing down to offspring of eyes of an inferior type. Indeed, the ordinary methods prevailing in schools of imparting knowledge promote the alteration in the shape of the eyeball produced by long convergence. It follows, then, that eyes of an inferior type or of faulty shape, when subjected to undue convergence strain, are more liable to suffer injury than are those which are of normal proportions and of natural acuteness of vision. In the face of such circumstances it is not unreasonable to come to the conclusion that many schools are manufacturers of defective vision. This question, as you will recollect, was first investigated by Cohn of Breslau, who examined 10,060 scholars and who published the results as far back as in 1867. Among the whole number he found 1072, or more than 10 per cent., short-sighted, and he found that the short sight increased steadily both in numerical prevalence and degree as the school life was persevered with, being less frequent and least pronounced in the elementary schools, more frequent and more pronounced in the intermediate schools, and most frequent and most pronounced in the finishing schools. His investigations have been since repeated by numerous observers in all parts of the world, with the result that notwithstanding variations in the percentage found in different localities the general statement made by Cohn concerning the progressive increase of short-sight in school-children, both in amount and degree, has been abundantly verified. Such an examination, as far as I can learn, has never been made in this colony, but each one of us is frequently meeting within our daily practice instances of defective vision in school-children. It is our duty, I think, as medical men, for the well-being of our colonial youth, to express our views clearly on the subject and to make suggestions whereby the abuse may be met. Dr. H. Lindo Ferguson of Dunedin in a most interesting paper read by him at the Inter-colonial Medical Conference, in the section connected with the eye, ear, nose, and throat, held in 1899 at Brisbane, came to the conclusion that in New Zealand the children attending schools were comparatively free from myopia, that for every case of myopia he observed more than 10 hypermetropes whose eyes had from one cause or another failed during school life, adding that "this freedom from myopia in New Zealand is not in any way due to special precautions on the part of the authorities to prevent it. ...... I can only consider that the small percentage of myopia is due to racial immunity from the condition." Mr. Brudenell Carter's statement to the Education Department in England in 1896 comes to the same conclusion, for he found that the ordinary refractive condition among 8000 children examined was hypermetropia. Mr. Priestley Smith in Birmingham found about 5 per cent. of short sight among 2158 school-children, the great majority being between the ages of eight and 11 years; but among 357 students in training colleges, persons taken from the same class, or nearly so, as the children, and of ages ranging from 18 to 23 years, he found short sight in 72, or what comes to 20 per cent. Mr. W. Adams Frost as a result of his examination of a South London board school found that 9·6 per cent. so suffered and Mr. Roberts has published the result of an examination of 596 boys held at Marlborough which made the percentage even higher still.

---

[1] The MS. of this paper has, owing to misfortune in the post, made three journeys between New Zealand and London before reaching us.—ED. L.

I do not propose to weary you by going into the pathological changes taking place in the eye as a result of carelessness in correcting (or doing nothing to assist) such conditions of refraction. Myopia is not only a most serious defect (although it is, curiously enough, a vulgar error to suppose that such a condition is more of a blessing than a curse), but it is a disease the nature of which is quite beyond our art to cure. At the same time, it is to an immense extent preventable and unless its progress can be arrested the eye must soon lapse into a condition of grave jeopardy. "Hypermetropia is congenital; myopia acquired." This statement is nearly correct, for myopia is but very seldom found in newly-born infants. The refraction of babes, as has been demonstrated by Horstmann, Ely, and others, is, pathologically speaking, that of constant hypermetropia. This condition alters and passes gradually into the emmetropic eye, or remains hypermetropic, or it passes into the myopic condition; the later state generally about the eighth year. Indeed, the myopes are recruited constantly by eyes which have passed over into this group from the hypermetropes.

Now it has been clearly established by the evidence set forth from statistics that defective vision is induced during the whole period of school life, and that children entering school with healthy eyes have developed faulty vision, and that the proportionate number of the scholars affected increase as we ascend in the classes and also in the grade of the school. Besides these undoubted facts regarding the effect on the eyes themselves the general nutrition and well-being of the body is sure to suffer on account of the necessity of bringing the eyes close to the work. The neck is bent forward, the chest cannot expand freely, and therefore the blood becomes imperfectly aerated. The brain will, after a time, not be supplied with healthy blood, and the bodily and mental vigour will accordingly suffer. This will explain how it comes about that such a large proportion of our New Zealand children appear to suffer from hypermetropia, due to defective nerve force for the accommodative effort, with pain in the eye and the supraciliary region.

The present South African war will of necessity call great attention to the eye. Indeed, the habit of seeing accurately is itself an education—it is the very best feeder of memory, and nobody with a perceptive eye can possibly be a dunce It is the duty, therefore, of a teacher to know how well or how ill each one of his pupils is provided with "eyes," because they are the chief portals through which instruction must be conveyed to him.

I will now pass on to consider what are the influences which act injuriously on the eyesight of school-children and what can be done to combat them.

The chief causes leading up to this defect are long continuance of close work with imperfect light, a stooping posture, work with brain and body fatigued, and indifferent type in the books perused. Mr. Bullar has recently drawn up tables with which it would be easy for any master or mistress to make a preliminary test which would hardly allow any serious defect of sight or high degree of hypermetropia to escape detection. The apparatus required for both tests is (1) a set of test types made for his tables by Curry and Paxton of London for the first and for test No. 2 a pair of spectacles with round glasses one and a half inches in diameter, with lenses + 1·5 D. The directions for the first of these tests are as follows. 1. Fix the card of letters in a good light which should be daylight. The child should stand with his toes on a chalk line 20 feet from the card. 2. Cover the child's left eye first and let the child attempt to read the rows of letters on the card from the top downwards. Enter in the column arranged for the purpose—viz., Column 6 (the first five columns being the number of the case, the date, the teacher's initials, and the name of the child)—the number which is printed on the test line of letters which the child can read perfectly. 3. Cover the right eye and enter in Column 7 the same particulars. As regards the second test, let the child put on the glasses and let the following directions be observed. 1. Cover the left eye (over the glass) and let the child read as previously and enter under Column 8 the number over the last line which he can read. 2. Cover the right eye similarly and proceed as before and enter in Column 9. Let the teacher note if the child may chance to see better with the glass or worse, or that the glass may make no difference. Now it is obvious under this simple examination that the first test excludes all practical important defects except long sight and that long sight is controlled by the second test. Column 10 is for the teacher's remarks on these tests, such as "cannot read well" or "has a squint," or the noting of any abnormality of the eyelids or eye, and the last column (11) is intended for the use of the medical man connected with the school, to whom the tables are sent when they are filled up. The tables are, of course, merely intended to ascertain the existence of defects of vision and not their nature. Such a test should be used in all schools, and the teacher should inform the parents of those children whose sight appears to be defective. If this were carried out we should see fewer cases of young men (as Mr. Bullar says) disqualified by defective sight after having suffered the process known as "cramming" for the army and navy, and, I may add, in New Zealand for employment which is quite unsuitable for them, in the railway department and in the marine service, in both of which services I regret to say that I have during the past few years been compelled to refuse the issue of certificates on account of various errors of refraction, especially to young men who have just left school.

### SCHOOL-ROOM REQUISITES.

In a school-room a good light is absolutely necessary, for a room which is badly lighted necessitates a close approximation of the pupil to his book and a still closer approximation for writing. What is very necessary, too, the light should be properly directed, for it will be of no avail, even if a room be well lighted as far as quantity goes, if the child be placed so that he reaps no proper advantage from it. It is well-nigh impossible to act up to the ideal in this direction, which would be to light all school-rooms from the roof. There can be no doubt that light proceeding from the left is to be insisted upon, because the very best position for anyone is to have the light passing over the left shoulder and somewhat behind. Light passing from the right must be objected to, because from the position of the right arm on the desk the point to which the attention of the scholar is directed is cast into the shade, and this is the exact spot where a really good illumination is imperative. No artificial light can replace daylight for the purposes of study, but when required artificial light should be abundant and steady; a flickering light is both fatiguing and dazzling, and if placed near to the eye the heat given out occasions great discomfort and is of course injurious. I understand that the electric light is now almost universally used in all high-class schools in England, for it is found that a room can be lighted up to an equal degree on all the desks by an arrangement of concave mirrors which throws the light up to the ceiling and is thus diffused equally through the room.

As to the desks and seating of the scholars, a bad posture is not only injurious to the eye but it is a frequent source of crooked spine. Eulenburg states that "90 per cent. of cases of curvature of the spine, not induced by local disease, are developed during school life; ...... that in a school at

Neuchatel among 381 girls 156 were found to have a more or less deviation of the spinal column" The proper seating of school children becomes, therefore, a very important *subject and of late years has received very great recognition* In the Paris Exhibition of 1867 only three school desks were shown, while in a recent one there was more than 70 displayed The manner in which the spine becomes distorted in sitting at a desk in a bad position—on a backless bench—can be readily demonstrated by any observant teacher by inking the spinous processes carefully and then placing the boy or girl at the desk in a faulty posture, the altered contour of the spinal column will at once be apparent A backless bench must be condemned, and desks and seats should be readily regulated according to the size of the pupil *Our object is to prevent undue approximation of the* scholar to the lesson book and at the same time to avoid stooping To bring this about the following essentials are emphatically necessary A back rest should be provided because a child will not sit for long upright The "rest' should reach up to the lower part of the back and no further If it did so it would interfere with the movements of the body and would favour a negligent reclining posture A footboard, too, should be provided if the scholar cannot easily reach the floor with his feet, because if his feet are compelled to "dangle" fatigue will ensue Indeed, the height of the seat, the desk and its slope are now attended to most carefully in all schools in England The slope for writing should be between 15 and 20 degrees, and for reading it should be 40 degrees Delay in establishing this desideratum in the schools of New Zealand should, in my opinion be regarded as mischievous In early life of course the bones are soft and easily moulded and even a slight but constant pressure brought to bear on them—be it ever so little out of the normal lines—may produce irremediable deformity It is consequently of the utmost importance that the desk, the form, the book, and the light should be so arranged that the scholar may have command over the subject in hand without fatigue and also without being compelled "to loll about" into vicious attitudes The pupil ought to sit equally on both buttocks, the head should be erect and the spine straight, and no unusual bending forward of the body should be permitted The forearms should be upon the desk about halfway to the elbows *This is the correct attitude* and should be insisted on The seats and desks as at present used are inadequate, because the present seating arrangement for the scholar prevents him from sitting correctly at work As a matter of fact, the only time the back rest is now used is when the pupil sits "idly" on the seat That there is great room for improvement in this direction is obvious, for the best possible posture should always be maintained while sitting, whatever the occupation of the moment may be The Glendinning adjustable modern school desk and seat will be found most beneficial for school children and even for many adults

As regards special dealing with the subject of early lateral urvature of the spine all that is necessary for me to say is hat the deformity should not be allowed the opportunity of making its appearance If it be slight immediate medical dvice should be sought and its further advance checked by n alteration of the level of the seat, and by absolutely orbidding study in the malplaced position, by joining in ut door games, and by methodical exercises of a suitable haracter with dumb bells or chest expanders All these xercises should be undertaken to the point just short of atigue, followed by rest on a cane deck chair with a sloping ack, which makes an ideal couch for a boy or girl so roubled.

### SCHOOL WORK

The mischievous influences which I have now mentioned vill act with greater force if associated with bodily fatigue and verwork, and more especially so if it be excessive brainwork t leads up to nervous exhaustion in which girls (especially etween the ages of from 12 to, say, 16 years) obviously suffer nost." Our present system of education entails much xhaustion and must cause us *to contemplate* as to what the esults will be, not only to the children in their adult life ut also to their children and the generations coming after hem Observant visitors to this colony, and more especially hose from England, are immediately struck with the number of our colonial girls who suffer from anæmia, and he cause of this condition will probably be found in our educational system and its general surroundings among the poorer classes Excessive hours of study mean extra strain The intervals of rest in the hours of study, even if short, should be frequent, and, what is of the very utmost importance to children, there should be a really good substantial midday meal *How many of our country school children get it? Many of them start the day's work by milking cows* before breakfast They hurry over this meal and run or ride to school—often a considerable distance—with their dinner, consisting of a few slices of bread and butter, in their satchels They work at their lessons far too long and walk or ride home weary and played out only to resume "preparation" for the following day after what is known as "high tea." As a matter of fact, I know, from evidence which I can rely upon, that children actually fall to sleep during school hours owing to real fatigue due to overwork, in the milking districts of this colony No wonder then that we see so many cases of *nervous instability, indigestion, carious teeth, and anæmia* in our colonial youth Apart from this cause the evil is first, the promotion of children from standard to standard by examination and secondly, the system of educational scholarships given in the primary and all of the secondary schools Under this system there is a tremendous temptation offered to teachers to "cram" their pupils for the annual examinations, seeing that their reputation as teachers depends on the percentage of their pupils who pass the examination The system of cramming is to be most heartily deprecated, for it can only lead to evil results You all *remember what the boy said* when he was asked by his mother, "What has become of your little brother?" "We were playing, he said, "to see who would poke his head furthest out of the window, and he won" Some triumphs are bought too dearly, since they are not likely to be repeated. I learn with great pleasure that something is now being done by the Education Department to check this terrible evil, and I trust that the measures adopted will be drastic There is no doubt that scholarships will continue to be competed for, and theoretically the system is all right, but its effects are extensive and in a variety of ways undesirable. We all appreciate the great advantages that the Education Boards in this colony offer to those children of the settlers in remote parts who show the ability for it, but it really means that if one or two boys (or girls) in a school are entered for one of these scholarships the rest of the class have to do the same work Consequently the penalty is paid by the rest of the class who are doing more work than they are able to do, and the result is that they may break down or become lazy spectators, seeing that they cannot digest the work of this standard These children unconsciously are really wise in their generation because they are reserving their bodies and minds for future use Nor does the evil end here because the class immediately below has to be prepared to take up the work of the scholarship class the following year, and the general standard of the whole school even down to the little ones, is regulated by an examination for which in all probability they will never enter As you all know, these Junior Education Board scholarships in the primary schools are only open to children under 13 years of age and failure in the Junior does not (provided the candidate obtains about 65 per cent. of the marks) debar them from competing in the Senior with the three years more education at school that it represents, and consequently those who have failed to obtain the Junior are during this interval straining every nerve to obtain the Senior prize which gives them their only chance of proceeding to a university career

Now, if one looks carefully into the course of study set for the highest class with the object of proceeding to a university degree in a girls' college or high school in New Zealand it means practically that when they have passed through it they have really aimed at a standard higher in some respects than that necessary for a pass B A degree. As a matter of fact, it is much more difficult to obtain a junior university scholarship in New Zealand than it is to proceed to a B A. degree which students are not supposed to reach until after a course of three years' extra study at the university In a recent issue of THE LANCET the statement was made that at the last B A. examination connected with the University of London (at which the average age of the women candidates is 23 years), out of 71 candidates 17 were manifestly anæmic (i e, 25 per cent.), 15 wore spectacles, and some 20 stooped or sat twisted or crooked, the reason being that the course of study is entirely sedentary

An odious system is prevalent in some schools It is the practice of pouring in a mass of undigested knowledge which is allowed to remain untested until the objectionable monthly or quarterly examination comes round. It is a sure sign of want of organisation and defective teaching. Every well-given lesson consists partly of teaching and partly of testing by cross-examination. Let the teacher revise the work done by all means, but do not subject the pupils to harassing and unreasonable examinations. The system adds extra strain on the child and only encourages cramming.

Now what is to be done to check these evils? I found that I could not answer this question to my complete satisfaction. I therefore consulted Miss Fraser, the head-mistress of the Wanganui Girls' College, a lady renowned for her organising capacity. Miss Fraser and her lady assistants are well known throughout the colony for their wonderful successes in the open competitive examinations and for at the same time keeping their girls in the very—to use a sporting phrase—"pink of condition." This is the ideal to aim at. Miss Fraser, to whom I am much indebted for her communication, has kindly permitted me to use her reply, which was as follows:—

Girls' College, Wanganui, Feb. 26th, 1901.

Dear Dr. Saunders,—You have asked me to give an opinion as to how the evils incidental to unwise competition for scholarships may be checked. I give my answer with a certain amount of diffidence and first shall strive to classify what have seemed to me the chief causes of evil in cases where harm has resulted from competition. The following covers all the cases I have known. 1. Poor physique on the part of candidate. 2. Undue ambition of parents forcing a child to take up work beyond its mental powers. 3. Unskilled teaching power and weak organising power on the part of teachers. Cause 1 might, I think, to some extent be met by requiring from candidates a medical certificate as to fitness. The drawback to this is that medical men as a body are so tender-hearted that they grant certificates when the ordinary lay observer would judge them unwarranted. Cause 2. Parents are usually very amenable to reason, and a word of advice from the head of a school is rarely taken amiss if sensibly given. Cause 3 is the most fruitful of all causes. In New Zealand there is absolutely no provision for the training of secondary teachers, most of whom approach their work with no conception of the laws regulating the human mind, very many of whom are without the sympathetic insight into mental processes that is much better than knowledge of mere laws. These teachers, having no idea of *training* minds and developing natural powers, simply pour in knowledge in a more or less crude form till the poor brain becomes clogged and breakdown follows. The obvious answer, then, to Cause 3 is that there is urgent need for more intelligent teachers.

Perhaps you will permit me to say that so far as my experience goes cases of illness are at least three times as numerous among the girls who do little as among the girls who do much work. This is, of course, as it should be, for the least work is given to the least fit. I merely state the fact for the sake of showing that mental work, properly regulated, does not lead to an undue proportion of sickness among the workers. The most exacting examination of our country is that for junior scholarships in the University of New Zealand, but suitable candidates can prepare successfully for that while never touching a book after eight or half-past eight in the evening and while spending at least three hours a day in the open air. With cricket, hockey, tennis, basket ball, gymnastics, swimming, croquet, cycling, and photography to keep the body in good condition it is surprising how much work a bright mind can accomplish. Trusting that my answer is not too lengthy,

I am, yours sincerely,
(Signed) M. I. Fraser.

The more I have contemplated over this letter the more satisfied I am that the writer's opinion is accurate. Not very long ago, in connexion with the examination for medical degrees in one of the British universities, it was remarked by someone in authority that examiners ought to be "angels from heaven." Probably the authority in question meant in wisdom and graces rather than in the possession of special medical knowledge. A similar idea must have entered not infrequently the minds of parents and guardians. There is, I believe, a real need—not so acutely felt as it should be—for the education of the educators. It is said, with a wise neglect of mathematical accuracy, that every child who is brought to a hospital on account of chorea has received physical punishment on at least three separate occasions—once for general restlessness and naughtiness, again for breaking crockery, and a third time for making faces at his grandmother. How often has an unfortunate child suffering from enuresis been subjected to active discipline on account of a supposed moral defect termed "laziness," when the real defect that needed a direct remedy was the over-acid condition of the secretions? How often has physical castigation been applied by affectionate friends to so-called hysterical children who are really passing through a post-epileptic state? It has been stated, somewhat dogmatically perhaps, that if we knew everything we would forgive everything. And it might equally well be said that if we knew everything we should actually punish the ordinary child little or not at all. You recollect what Sir Samuel Wilks—when called in consultation to see an imbecile child who had been given all sorts of medicines, some presumably atrocious in flavour, by the conscientious person in attendance—*asked*, if it was expected thereby to produce an additional cortical convolution. "One of the early steps in the wise education of children is to recognise their limitations before exhibiting moral treatment."

There is no one who admires our army and navy more than I do, but the Imperial troops in one respect set our colonial boys a very bad example during their recent circuit through New Zealand. I refer to the absurdly tight-fitting uniforms worn by the officers and men. It is pitiable to see this existing at the commencement of the twentieth century, which prides itself on being civilised and scientific, for it is as certain as any proposition can be that the breathing organs and the limbs should have free play. One might expect such fads from foolish young ladies with pinched-in waists and wriggling gait engendered by that modern abomination of abominations, the abdominal corset, and the modern boot, which are regarded with so much contempt by all sensible men and women. There is now at the head of the War Office a strong, sensible, and practical man, and I venture to predict that ere long we shall note that Lord Roberts will revolutionise the attire of our soldiers even when on parade, for it is a known fact that if a number of soldiers and sailors take a long march on a sweltering day many of the former will fall out and not one of the latter.

### INFECTIOUS DISEASES IN SCHOOL LIFE.

Of all the absolute pests of school life, infectious diseases must be placed first and foremost. When a serious outbreak occurs the schoolwork for the time being is demoralised. I consider that in all boarding-schools an infectious ward, isolated far away from the main building, should be insisted upon, because if this provision be made any suspicious case suddenly arising can be immediately isolated and its accurate nature soon determined upon and the necessary precautions taken. How many boarding-schools in New Zealand have such a ward? The so-called infectious ward is generally placed in, or is really a part of, the main building. The usual rules concerning infectious cases occurring during the holidays should be strictly enforced. It ought to be regarded as criminal for any parent to send his son or daughter back to school who has recently been the victim of any of the exanthemata without a certificate from a medical man that everything has been done in every direction to make the pupil's return safe and secure. This is a course, I believe, which is not at the present time carried out as it should be.

### CARDIAC STRAIN IN SCHOOL-CHILDREN.

Cardiac strain is met with in school-children. It causes sudden definite and occasionally alarming symptoms which need special attention at the moment and care also of a continuous nature during school life. Many of these cases are, I am satisfied, "cured" by care; but, if neglected, they are prone to run a terribly rapid downward course. The question then arises, What kind of work and play may be permitted? Prognosis, of course, depends upon the valve involved, and the future line of action as to what rules and restrictions should be carried out must remain entirely at the discretion of the medical adviser, and these instructions must be rigorously enforced. In the majority of cases it will be found sufficient to exercise ordinary care, for the boy will be passing through the period of puberty when radical organic changes are being worked. As long as "compensation" keeps up and the bodily vigour is encouraged by suitable exercises "a prominent murmur, instead of sounding the death-knell, is a subject for congratulation," as Sir William Broadbent long ago pointed out. As a matter of fact, the pupil so troubled must not be kept in a glass-case; he should be encouraged to walk in the middle of the road, exercising his body according to his general condition and under the guidance, as I have already stated, of the medical adviser who will prescribe those exercises which are suitable and condemn those which are not. I attended a schoolboy about 10 years ago who had met with an accident, and in the course of my investigations I discovered a systolic murmur. I prescribed the usual routine of exercises suitable for him, but, like a boy, he soon forgot all about his trouble. In due course he went to Cambridge and it was only when he found that he had a certainty of rowing in the trial eights and a reasonable chance of getting into the Cambridge boat that the extra strain necessary for the occasion was brought home to him. He then, he told me, remembered my remarks, and, seeking advice, found it necessary to retire from the position which he had hoped to attain.

### DEAFNESS IN SCHOOL-CHILDREN.

A condition of deafness in school-children is occasionally responsible for what teachers, from want of knowledge, may consider to be gross inattention or stupidity on the part of their pupils, and many a poor boy and girl has been punished when no punishment ought to have been inflicted. We all know the "vacant expression" brought about by adenoids and nasal obstruction and the dull, stupid look of the child so often accompanied by deafness. These are evils which, if left to themselves, cause in many instances future disaster, and teachers should be acquainted with the characteristics of these complaints and report accordingly. I look upon it as criminal for any teacher to "box the ears" of his pupil; it is a most reprehensible practice and occasionally it leads to serious disaster. There are other places for inflicting punishment: the ear is to be respected. I have heard it said that teachers never act in this way now. I trust that this statement is a universally accurate one, but that some parents continue this barbarous practice is certain, for I have been an eye-witness of the atrocity quite lately.

This is no world for lazy, stupid, and indolent people. Unless a boy works honestly at school he will have in this era of competition but a poor chance in the battle of life as fought nowadays. Both boys and girls, especially of the poorer classes, should be placed under much greater parental control than they are at present. We would then hear of less sad cases of disaster occurring which are due in by far the majority of cases to this neglect.

### CONCLUSION.

Boys and girls should wear suitable boots. Boots and shoes too narrow and too short produce deformities of the feet which lead to physical misery in advancing years.

I originally intended to devote a considerable portion of this address to a consideration of outdoor games in schools. I find that I have already occupied too much of your attention and I will merely say that in the secondary schools of New Zealand and in the various colleges school sports of every description flourish. Immense advantages accrue to those engaging in them, for the moral influence of sport is to be regarded even higher than mere physical power and alertness. Outdoor games develop mutual control, command of temper, and honesty. It is a matter of satisfaction to find how much games are encouraged in our girls' schools. ootball, our most popular game, I believe, brings out all ie qualities that ought to be innate in a brave soldier. hat I think, to a large extent explains how it comes about iat our boys in South Africa have rendered such an xcellent account of themselves and have added lustre to ie "Britain of the South."

The age in which we live is one of keen international ompetition, and the prize must ultimately be gained by that ation which, possessing great physical vigour, natural esources, or acquired means of sustenance, finds its oppor-unity in equable development of mind and body, in strict dherence to that which is right, in patience and persistence, nd in the avoidance of all causes that lead to physical, aoral, and mental degeneracy, for evolution proceeds apace n nations as in individuals.

---

**THE HEALTH OF LEICESTER.**—During the past l2 months the following certificates of infectious disease vere received for the borough of Leicester: Diphtheria, l080; scarlet fever, 764; erysipelas, 194; typhoid fever, l38; puerperal fever, 11; and small-pox, 4; total, 2191.

**LONDON HOSPITAL MEDICAL CLUB.**—A meeting of the London Hospital Medical Club and its annual dinner ook place on Dec. 31st, 1901, at the Café Royal, Regent-street, W. Dr. Albert S. Morton of Putney occupied the chair, and was supported by Dr Sansom, Dr. Herman, Mr. T H, Openshaw, and others Dr Morton, in proposing the toast of "The King" pointed out that His Majesty had peculiarly honoured the medical profession by accepting the Fellowship of the Royal College of Physicians of London and of the Royal College of Surgeons of England, and that so far as tuberculosis and cancer were concerned, the knowledge of the King was equal to that of any medical man present The company separated at 11.30 after a most enjoyable evening. The members of the club voted that a sum of 10 guineas should be given to the fund now being raised for the benefit of the family of the late Mr. William Smyth who so heroically sacrificed his life.

# A Clinical Lecture

ON

# ACUTE SUFFOCATIVE PULMONARY ŒDEMA.

*Delivered in the Glasgow Royal Infirmary on March 8th, 1901,*

BY JOHN LINDSAY STEVEN, M.D.,
F.F.P.S. GLASG.,
PHYSICIAN TO THE GLASGOW ROYAL INFIRMARY, LECTURER ON THE PRACTICE OF MEDICINE, QUEEN MARGARET COLLEGE, UNIVERSITY OF GLASGOW, HONORARY LIBRARIAN, FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW, ETC.

I INTEND this morning to direct the class's attention to acute suffocative pulmonary œdema, an affection which may suddenly plunge the patient into the most acute agony, and in a short time place his life in the gravest jeopardy. Fortunately, it is a disorder which is but rarely met with, but on that very account it is necessary that you should be acquainted with its leading phenomena, in order that when a case does occur in your practice you may not be taken by surprise and may be able to do the most that may be done for the relief of the patient

Œdema of the lungs in its more chronic forms is a morbid state which is well known to, and easily recognised by, both the pathologist and the practical physician. It is, however, almost invariably a secondary or complicating condition the importance of which is quite subsidiary to that of the primary disease by which its incidence is determined. The chronic and even subacute forms of pulmonary œdema are usually met with in the course of cardiac, pulmonary, renal, and febrile diseases, and in the case of the specific fevers and diseases of the heart more particularly it is not infrequently associated with that passive hyperæmia of the lungs to which the name "hypostasis" is usually applied. The symptoms and the post-mortem appearances of this form of œdema of the lungs are very well known, and you will find them described in greater or less detail in all the well-known text-books of medicine Your attention has frequently been directed to the symptoms of chronic pulmonary œdema in the course of our ward visits

The affection of which I mean to speak, however, is of a different kind—at least as to its chief clinical phenomena. It can only be called "acute suffocative pulmonary œdema" and you will look in vain in most of your books for a description of it If you look through a sufficient number you will find here and there short references to acute œdema of the lungs, but no detailed descriptions. Some of these references indicate a condition similar to that of which I am now speaking, but it is difficult to be sure. Hilton Fagge[1] speaks of "an œdematous inflammation of the lungs which comes on acutely and without previous disease," and gives references to "marked and severe cases" which, however, he says, "are rare." On consulting the accounts of the cases to which he refers I find that they are hardly of the same character as that which I am about to describe. To our case the term "œdematous inflammation" would not apply, as you will shortly see Kingston Fowler[2] says that "cases are occasionally observed in which œdema of the lungs supervenes with remarkable rapidity during an acute illness of sudden onset" He relates briefly one case in which enormous quantities of frothy fluid were expectorated after three days of illness characterised by fever and pain in the chest. The nature of the case could not be determined and it was classified in the post-mortem reports under the head of "acute pulmonary œdema." Neither is this case similar in several particulars to those which I am about to relate. Strumpell[3] says: "In very rare cases, as we have seen, an apparently primary acute pulmonary œdema with a speedily fatal termination develops in men who were before that apparently perfectly healthy and the necropsy gives no further explanation of its origin. We probably have to do in these cases with the sudden failure of the left ventricle." Dieulafoy,[4] under the heading of "*œdème brightique du poumon,*" gives a detailed account of a case very similar to that which is the text of this lecture. The description given by this distinguished physician of his case of acute pulmonary œdema and his subsequent analysis and discussion of the symptoms are the most thorough and complete that I have met with. It is unnecessary to refer further to the literature of the subject and I shall now relate to you the clinical history of a very striking case of acute suffocative pulmonary œdema, as it is recorded in the ward journal. You have frequently examined the patient with me in the ward although you did not, as I did, see her in the depth of her agony. As the patient left for her own home in the North of Scotland yesterday I can now submit to you the full clinical report of the case, after which I shall recall to your memories the history of another patient whom you saw earlier in the session and who had several attacks of this affection—"*cette terrible complication,*" as Dieulafoy calls it—the last ending in death. Having described the cases I shall offer to you a few remarks on the symptoms, diagnosis, and treatment.

[1] Text-book, third edition, vol. I., p. 1002.

[2] Diseases of the Lungs, p. 221.

[3] Text-book of Medicine, second American edition, p. 183

[4] Pathologie Interne, thirteenth edition, tome I., p. 282.

The following are the clinical notes entered in the ward journal by my resident assistant, Mr. E. H. Roberts:—

Case 1.—"A woman, aged 38 years, was admitted into the Glasgow Royal Infirmary in a somewhat collapsed and highly dyspnœic condition at 2 30 A.M. on Jan. 29th, 1901. She had retired to rest at 11 P.M. in her usual health. Shortly afterwards she felt that she could not get her breath properly, and attempted to improve matters by first lying on her left side, then on her right side, and lastly in the dorsal decubitus, but all to no purpose, the difficulty of breathing becoming rapidly worse. The dyspnœa was increased in a short time by frothy material coming up her throat which was chiefly whitish and at times pinkish in colour. The frothy fluid was expectorated in considerable quantity, the patient in the intervals gasping for breath. At this time severe lancinating pain was experienced across the front of the chest. A loud wheezing in the chest during the respiratory acts was observed by her. The patient was housekeeper to an old bachelor friend of Dr. Lindsay Steven who saw her at midnight and advised her removal to the Glasgow Royal Infirmary, whither she was removed in a cab. During the journey her condition was so critical that at times it was feared she would have succumbed. Upon admission she was gasping for breath. The face was somewhat flushed, the lips were livid, and she was freely expectorating a whitish frothy sputum. There was no cough. The respirations were noisy and wheezing, were greatly embarrassed, and numbered 34 per minute. The pulse was small, rapid, regular, and numbered 105 per minute. The temperature on admission registered 96·4° F., at 8 A.M. 99·8°, at noon 99·6°, at 4 P.M. 99 4°, at 8 P.M. 99 4°, and at midnight 98·6°. On auscultation of the chest, as quickly as possible, it was found to be the seat of fine and medium moist râles. By 6 A.M. she had sufficiently recovered to be bathed in bed, and by 9 A.M. she was able to lie down, her head being supported by two pillows, and henceforth she continued to make rapid and steady progress.

"*Jan. 30th.*—To-day the patient was almost herself again and it was possible to make a formal clinical report.

"*Past history.*—The patient states that she had always enjoyed good health until the onset of the present attack. She had never noticed any swelling of her face, but had noticed some swelling of her feet and ankles at night occasionally which she attributed to her having to be a great deal on her feet. She had never had any urinary trouble, not having noticed anything unusual in the quantity or appearance of her urine. She had been subject to headaches occasionally. There had been no nausea or vomiting, no anæmia, or general weakness. Her appetite had been fair.

"*Family history.*—Her mother is alive and well. Her father is dead, the cause of his death being unknown. She has two brothers who are alive and well.

"*Present condition.*—Decubitus is dorsal and quiet. She is well developed and of fair nutrition. The pupils are equal, medium, and react normally. The lips and mucous membranes are of normal colour. The tongue is moist and coated irregularly with a greyish fur. The respirations are quiet and unembarrassed, and number 26. The pulse numbers 76 per minute, is of fair volume, medium tension, and regular. The temperature is 98·6°. There is a highly varicose condition of the veins of the right lower limb, with brownish discolouration of the middle and lower thirds of the leg.

"*Respiratory system.*—The chest is well-developed and symmetrical, while the respiratory movements are of normal excursion. On examination nothing abnormal with the exception of an occasional moist râle is detected, the respiratory murmur being of normal vesicular quality.

"*Circulatory system.*—The apex beat is somewhat heaving and diffuse and located in the fifth interspace, three and a half inches to the left of the mid-sternal line. The præcordial dulness has the following limits: upper, upper border of the fourth rib; right, three-quarters of an inch to the left of the middle line; left, three and three-quarter inches to the left of the middle line. The greatest transverse measurement is three inches. There is accentuation of the second sound in the aortic area, while the first sound in the mitral area is somewhat low-toned; otherwise the cardiac sounds are pure.

"*Abdomen.*—The hepatic dulness cuts the sixth rib in the mid-clavicular line and measures vertically three inches. No splenic enlargement can be detected. On examination no abnormality is detected.

"*Alimentary system.*—The tongue is moist and coated irregularly with a greyish fur. The bowels are regular, but the appetite is indifferent. The urine is acid, its specific gravity being 1022; it is clear amber in colour, and there is a slight flocculent deposit. Microscopically hyaline and granular tube casts, leucocytes, and squamous epithelium are observed. Albumin is fairly abundant. The tests for sugar and blood are negative.

"*Feb. 1st, 1901.*—Since Jan. 30th there has been marked and steady improvement. The patient is now practically well. The temperature has ranged between 98·6° and 99°. The respirations have varied between 24 and 32, and the pulse between 68 and 78. She sleeps well and her appetite is fair. The bowels are regular. It has been impossible to estimate the amount of urine passed owing to some being lost."

The following note was made by me on Feb. 5th. "The whole course of this case indicates that the patient has been suffering from acute suffocative pulmonary œdema associated with acute renal disorder, as evidenced by the albuminuria and tube casts at the time of admission. Very great improvement is now to be recorded. Absolutely no trace of albumin is found in the urine this morning, which to the naked eye presents perfectly healthy appearances. The temperature throughout has been normal, and the quantity of urine on the whole somewhat less than usual. There is perhaps very slight accentuation of the second aortic sound and quite distinct of the second pulmonic. The first sound at the apex is slightly muffled in character and the apex beat is very vaguely palpable in the fifth interspace four inches to the left. Posteriorly pulmonary percussion is normal and the respiratory murmur presents healthy characters back and front."

The clinical notes continue: "*Feb. 12th.*—Since the above record the patient has remained practically well. Her appetite to-day is good, the urine is normal, and the bowels are regular. On examination of the lungs nothing abnormal is observed. The cardiac condition remains much as in the previous note. She is now allowed up daily, a Martin's elastic bandage being worn for the varicose condition of the veins of the right lower limb.

"*March 7th.*—Since the previous record the patient has remained quite well. The lungs, on examination, are found to be quite normal, as is also the heart. The urine is entirely free from albumin, and microscopically nothing beyond an occasionally squamous cell is to be observed. She leaves for her home in the north, feeling quite well."

The clinical record which I have just read to you may be taken as a very characteristic history of an almost pure case of acute suffocative pulmonary œdema occurring in the midst of apparent health and associated with renal disorder of a temporary character. Before offering some general remarks on the subject under discussion, I wish briefly to summarise for you the leading phenomena of a case which we have frequently examined together and in which the attacks of suffocative pulmonary œdema were but incidents in the development of a chronic cardiac and renal disorder.

Case 2.—The patient, a man, aged 40 years, was admitted into the infirmary for the first time on Dec 27th, 1899, on account of swelling of the legs of a month's duration, and shortness of breath on exertion, cough, and expectoration of a fortnight's duration. It is unnecessary to go into the clinical history in detail. It is sufficient to say that the man was found to be the subject of aortic obstruction and regurgitation and of mitral regurgitation. In addition the presence of albumin, blood, and granular tube casts in the urine indicated a subacute nephritis, probably of tubular character. These parts of the case were frequently made the subject of clinical demonstration in the wards during both his first and his second residence, the latter beginning on Nov. 23rd, 1900, and ending with his death on Jan. 27th, 1901. At present we are interested in these elements of the case in so far only as they were complicated with attacks of acute suffocative pulmonary œdema, and I shall from the ward journal read to you the accounts written at the time of the first and the second last seizures. You will at once recognise that the paroxysms were in all respects similar to those occurring in Case 1, although, unlike the attack in that case, they did not come on in the midst of perfect health.

"*Dec. 30th, 1899.*—To-night, at 7.25 P.M., the patient was suddenly seized with great dyspnœa He was terribly distressed for breath and plucked at the clothes on his chest. His face was cyanosed and the veins of the neck were distended. The pulse during the attack numbered between 150 and 160 and was full and bounding. There was a good deal of rattle in the trachea and he spat up copiously a white frothy material which later became pinkish. Amyl nitrite and inhalations of oxygen were administered with some relief, after which the pulse numbered between 120 and 130 The heart was beating very forcibly and the chest was full of râles. A hypodermic injection of strychnine ($\frac{1}{30}$ grain) was given. The patient still continued very breathless. His body was cold and covered with a profuse clammy sweat. The pulse continued about the same rate but varied greatly in force. Additional inhalations of oxygen seemed to give but little relief and stimulants were refused. The sputum became very profuse and was more distinctly red. *About 9.15 P.M. strychnine ($\frac{1}{30}$ grain) was again given* hypodermically. Dr. Lindsay Steven was telephoned for and saw the patient at 9.30 P.M. when the condition was much the same Since then he has had brandy both hypodermically and by the mouth. At 11.30 P.M. the patient was still very ill and breathless. The pulse was fairly good and numbered about 140. His sputum was rather less profuse but distinctly red. The body surface was warmer and the sweat much less.

"*Dec. 31st.*—About 2 A.M. the patient began to recover from the seizure described in the foregoing note. Dr. Lindsay Steven from his own observation confirms the accuracy of the account, and taking all the phenomena into consideration is on the whole disposed to think that the seizure has probably been caused by embolism of one of the large pulmonary branches. The blood-stained and highly frothy sputum with the excessive struggling for breath were indicative of an acute pulmonary œdema, and the presence of the renal disease raised the question as to whether the whole seizure might not be uræmic in origin. The discovery this morning of distinct dulness at the right base below the scapula and of numerous fine, moist, crackling râles, chiefly inspiratory, and of a distinct bronchial respiratory murmur, is a strong indication in favour of embolism. At 3 P.M. the patient complained of cold but had no actual rigor. His pulse at 4 P.M. was 124 per minute *and his respirations* were *50. His temperature* was 103.6°. He was not expectorating so much but the sputum was very bloody. He continued much the same and at eight o'clock his pulse was 120 and his respirations were 60 per minute. When seen at nine o'clock he was lying on his right side The body surface was very warm and the skin was covered with sweat. The pulse was 132 and the respirations were 60 per minute; the breathing, however, was not very distressed. There was still a good deal of rattle in the trachea.

"*Jan. 11th, 1901.*—Last night about 7.25 P.M. the patient passed into a dyspnœic attack in all respects similar to that described in note of Dec. 30th, 1899 The seizure lasted until 2 A.M. and was accompanied by a frothy bloody expectoration to the extent of 26 ounces. During the seizure the respirations numbered 56 and the pulse 160; the chest was full of snoring and wheezing rhonchi; and the patient had to sit up, being unable to remain in bed. When the violence of the paroxysm had passed he was able to return to bed, but not to lie down, and in the sitting posture obtained short snatches of sleep. The expectoration examined this morning consisted of three parts—(1) a large amount of pink and white froth which floats on (2) a thin watery tea-coloured fluid, and, (3) of a very small amount of blood-clot at the bottom of the spittoon. The physical characters of the expectoration can only indicate acute pulmonary hyperæmia and œdema. This morning the apex beat is found in the fifth interspace five and a half inches to the left, and is abrupt and slapping in character. The cardiac area is greatly increased, particularly to the right. Right border two and a half inches to right of mid-line; left border five and a half inches to the left at level of fifth interspace. Upper border is at level of upper margin of fourth cartilage. A loud superficial ventricular systolic murmur is heard at the apex and faint ventricular systolic and ventricular diastolic murmurs in the aortic area. At the right base posteriorly, from the level of the sixth dorsal downwards absolute dulness on percussion is obtained, and in the area numerous fine crackling râles with inspiration are heard. Similar crackles are also obtained at the left base. Throughout the present residence the temperature has been normal or subnormal and the average daily quantity of urine rather above than below the normal amount The amount of albumin has averaged about 2 per cent (Esbach) and a trace of blood has always been present."

The patient died in a similar attack on Jan. 27th, 1901; and I now read to you Dr. C. Workman's report of the post mortem examination

"*Post-mortem summary.*—Subacute tubular nephritis; chronic changes in aortic valve; stenosis of mitral valve; and congestion of other organs.

"*Post-mortem report* —A well-developed and well-nourished body, rigor mortis still present. There is well-marked œdema of the lower extremities. The heart is enlarged. This is chiefly in left ventricle. The pericardium contains a considerable quantity of serous fluid. The pulmonary valve is competent; the aortic is incompetent. The pulmonary *curtains are* healthy. The aortic curtains are considerably thickened, especially along the margins. The right curtain and the adjacent portion of the posterior are infiltrated with lime salts. There is a large thrombus pyramidal in shape adhering to the margin of the posterior curtain. The endocardium over the septum immediately below the right aortic curtain is thickened over an area of about one inch square. The left ventricle is dilated and the wall is considerably hypertrophied. There is stenosis of the mitral valve and great thickening along the margin of the curtains. There are several small thrombi on the auricular surface of the valve. The left auricle is dilated. The right ventricle shows some hypertrophy and the right auricle is also dilated Coronary arteries present one or two small patches of atheroma Cardiac muscle is of good consistence and colour Both pleural cavities contain a quantity of serous fluid. Both lungs present a number of adhesions to the chest wall. Both are deeply congested and œdematous and there is no evidence of pulmonary embolism or thrombosis. The liver is enlarged and presents a nutmeg appearance. The spleen is enlarged and congested. Both kidneys are enlarged, the capsules being non-adherent. The surface presents a mottled appearance, the yellow of the mottling being due to a fatty degeneration of the tubules. The left kidney presents slight hydronephrosis. No obstruction is found in the right ureter. The aorta presents a per*fectly healthy* appearance. The brain presents nothing unusual. The stomach and intestines are healthy. The weight of the organs is as follows: heart 19 ounces, right lung 39½ ounces, left lung 40 ounces, liver 80 ounces, spleen 13¾ ounces, and the right kidney and left kidney together 20½ ounces."

### SYMPTOMS.

I have thus described to you, from the actual clinical notes written at the time, two cases of a morbid state which I have ventured to call "acute suffocative pulmonary œdema," and I think that you will agree with me that here we have an affection which might well find an independent place in nosology. The clinical phenomena of both the cases are striking and distinctive, but they differ perhaps in this, that the one may possibly be regarded as a primary and the other certainly as a secondary or complicating condition. The onset of the symptoms in Case 1 was so abrupt and the disappearance of the signs of renal disease took place so rapidly that we are perhaps justified in regarding the acute suffocative œdema of the lungs in this case as primary and the albuminuria as perhaps the effect rather than the cause of the pulmonary affection. As regards the second case there can be no reasonable doubt that the acute pulmonary œdema was merely a complication of the chronic cardiac and renal disease from which the patient was suffering. Whether this view as to the nature of the two cases just described be correct or not, it may be granted that Case 1 was primary inasmuch as the pulmonary symptoms set in in the midst of apparent health and inasmuch as the renal symptoms disappeared with the pulmonary symptoms.

The symptoms of acute suffocative pulmonary œdema are so striking that there is, on the whole, but little difficulty in recognising their significance, especially after one has had the opportunity of seeing a case. Without warning, and without, as in our two cases, any over-exertion or excitement, the patient is suddenly seized with great difficulty of breathing accompanied by a sense of intense oppression behind the sternum. It is quite impossible for him to lie down, and almost simultaneously with the onset of the dyspnœa—a most important diagnostic point—expectoration of a perfectly white, finely frothy, watery sputum begins. The frothy fluid seems to flow up the trachea, and is expelled with a "hawk" as if clearing the throat, but there is no cough in the ordinary sense of the word. The sputum continues during the whole period of the dyspnœa and the seizure is not usually accompanied by fever. The pulse may be very rapid; and wheezing and fine moist râles are everywhere heard. The extremities soon become cold and blue, the face is ashen grey, and the agony and anxiety of the patient are extreme. After a little the frothy sputum becomes slightly pink in colour, and in some cases, after the attack has lasted for an hour or two, definitely bloody. In the course of five or six hours as much as one and a half pints of this frothy fluid may be expectorated. Such is a brief description of a morbid state which I can only interpret as significant of acute suffocative œdema of the lungs. The whole clinical phenomena indicate that the pulmonary alveoli are suddenly inundated with watery serum, and it is quite conceivable that such a condition might prove very rapidly fatal.

### DIAGNOSIS.

Notwithstanding the characteristic nature of the symptoms, it is necessary to say something about differential diagnosis, as there are several forms of acute dangerous dyspnœa with which that of acute pulmonary œdema might be confounded, and to which I shall now briefly refer.

1. *Pulmonary embolism.*—The first thing that occurred to me on seeing both of the cases described in this lecture was that the patients were suffering from embolism of some of the larger branches of the pulmonary artery. Indeed, in Case 1, so strongly did the patient's general condition resemble that of pulmonary embolism that one of my first questions to her was, "Have you got bad varicose veins?" As we have seen she was the subject of great varicosity of the veins of the right lower extremity. In Case 2 the presence of valvular heart disease and the development subsequently to the seizure of dulness and moist râles at the base of the right lung suggested a diagnosis of pulmonary embolism. The subsequent course of both cases negatived such a diagnosis, and in Case 2 the necropsy revealed no evidence of embolism. The symptom which in my opinion establishes the diagnosis of acute œdema of the lungs as against pulmonary embolism is the rapid development, practically coincident with the onset of the dyspnœa, of white, frothy, watery expectoration which afterwards becomes slightly pink in colour. In embolism expectoration is a later development and when it is established the sputum is definitely bloody from the first.

2. *Acute spasmodic asthma.*—This is a condition which might be thought of in the presence of symptoms such as I have been describing. In asthma, however, although the distress of breathing may be very great, there is no expectoration during the attack, the expectoration only being established when the dyspnœa is passing off and usually being limited in amount to a few sputa of grey mucous pellets.

3. *Uræmic asthma of the ordinary type.*—This is usually not so severe as that which we have been considering, it is not so sudden in onset, and it is unaccompanied by the profuse frothy sputum or by marked physical signs of pulmonary œdema. Its occurrence, also, in the course of well-marked renal disease, usually of a chronic type, distinguishes it from the severer form of respiratory distress such as occurred in Case 1.

4. *Acute pulmonary œdema.*—This, with abundant watery expectoration, following the removal of large pleural effusion by the operation of paracentesis thoracis, is a condition which somewhat resembles, as regards the expectoration at least, that with which we are at present concerned. On one occasion I have seen this complication in a case where I had removed a large pleural effusion by tapping, but although the amount of expectoration was very large and the spitting lasted for nearly 24 hours there was none of the severe respiratory distress which was so alarming in the two cases of acute suffocative pulmonary œdema which I have narrated above.

### TREATMENT.

This is all that I need say on the subject of diagnosis, and a few remarks upon the treatment to be adopted will form a fitting conclusion to this lecture. Both of these cases were treated by free stimulation, and I think that is the first therapeutic procedure which would naturally suggest itself to the practitioner on witnessing the state of collapse into which the patient soon passes. On account of the great dyspnœa and the overpowering sense of suffocation caused by the continuous flow of fluid from the trachea into the mouth the stimulants are better administered hypodermically and by the rectum. An ounce of brandy may be injected into the rectum diluted with an ounce or two of water or beef-tea. At the same time a hypodermic injection of strychnina ($\frac{1}{60}$ grain) and of digitalin ($\frac{1}{100}$ grain) may be administered. The patient should be kept absolutely at rest in the sitting posture. A sinapism over the præcordium is of assistance, and the extremities should be kept warm by hot bottles. Opiates in any form are, I think, to be avoided as tending to prevent the expulsion of the œdematous fluid from the pulmonary alveoli. The injections may be repeated, if necessary, in three or four hours. If the patient is able to swallow, diffusible stimulants such as sal volatile are certainly to be recommended, and small quantities of milk, beef-tea, and brandy from time to time.

The propriety of blood-letting also suggests itself in considering the treatment of acute suffocative pulmonary œdema and is favourably spoken of by Dieulafoy. The blood may be taken either at the arm or by wet-cupping of the chest. The depression and collapse, however, are frequently so extreme that I confess one hesitates to deplete. In spite of this Dieulafoy thinks it should be tried, and certainly from the point of view of a possible mechanical relief to the labouring heart it is a procedure which might be justified. In the first instance, however, I would advise free stimulation in the way which I have described.

---

# An Address

ON

# MENTAL SCHOOL HYGIENE.

*Delivered at a Conference of Science Teachers arranged by the Technical Education Board of the London County Council on Jan. 9th, 1902,*

BY FRANCIS WARNER, M.D., F.R.C.P. LOND., F.R.C.S. ENG.,

PHYSICIAN TO THE LONDON HOSPITAL, ETC.

LADIES AND GENTLEMEN,—School hygiene considered as a science deals not so directly with the children as with their environment; it includes all circumstances which may affect the children and their teachers beneficially as distinguished from those conditions which are inimical to healthy growth and development. The care of the body and the well-being of the children come within the departments of public medicine and sanitation, while the culture of the mental aspects of a complete and healthy life necessitates the careful study of education, as well as scientific training with knowledge on the part of those whose duty it is to guide the teaching and care of children.

A connecting link between the various aspects of school hygiene is supplied by the study of the children themselves after the scientific methods employed in natural history. My present purpose is to show that mental science, founded upon the observation of facts seen in school-children, may furnish us with exact knowledge concerning methods of procedure in training, while sanitation is directed to the prevention of disease and bodily ill-health. Hygiene must be studied in its effects upon the children; but children differ greatly and it has been shown that the environment and educational methods of a school act differently upon various groups of pupils. We should, then, study not only the education required in a school, but also consider the special adaptations that may be needed for certain groups of children who may somewhat differ from the average in mental or physical status Those who habitually observe children will soon gain a practical acquaintance with their varying brain conditions and note points indicating good and intelligent action as well as faults or disorderliness, and thus become able to infer from what is seen the adaptations of method that are needed in training an individual child and building up true character.

The hopeful signs of mental aptitude and capacity for education as commonly seen in children are (1) spontaneity in movement and action; (2) control through the senses, leading to imitation of the teacher and coördinated action; (3) receptivity and retentiveness of impressions produced upon the brain (memory); and (4) response in action and later in the use of words the meaning of which has been gained by experience, showing intelligent mental action under guidance. Thus, we wish to see a lively facial expression with activity, talkativeness, and liking to take part in organised games and occupations, as well as good imitative power and accuracy increasing with practice. For mental healthiness and strength the child needs experience of mental impressions, graduated and connected under the control and guidance of his teacher—stage by stage—leading to coördinated brain-power such as may afford self-control and volition adapted by, and therefore in harmony with, the varying circumstances of adult social life.

The principal means of controlling the brain and producing in it those impressions which give the child an experience useful in subsequent education are through the eyes, the ears, and by muscular sense. The brain produces all movement and expression seen in the child; it is desirable early—before the use and meaning of words has been fully attained—to train movements in the young pupils; in other words, we seek to train the faculties of "attention," "controllability," and "response" at an earlier period than it is possible or advisable to give instruction and to impart knowledge. This should be the work of the kindergarten, where speech with the proper use of words may be acquired without books, and training is more useful than learning to read and write; and let me add, this may be accomplished without destruction of that healthy brain spontaneity which is the basis of potentiality for education. This elementary training in the infant school is most necessary; good mental faculty is not acquired by children left untrained and with nothing to do all day. In the training college no subject of study is more important for teachers than a knowledge of children based upon observation and scientific principles. Observation shows that some children are controlled more readily by sight than by the spoken word of direction; the former class of pupils are kept under better discipline by a signal intimation (sight) of what is required of them, than by a command to "go on," which may cause mental confusion and fidgetting. This mode of discipline is used practically in schools for the deaf. Training should proceed stage by stage, so as to preserve and to cultivate mental health and growth. Thus eye-drill is needed to obtain the power of accurate seeing, before learning to read, to write, and to work sums. Inaccuracy in arithmetical work on paper or the blackboard, in reading, spelling, and in transcription, is often due to irregular movements and want of control of the eyes; if they are directed towards the wrong figure or word a mistake results, but eye-drill tends to prevent such errors which are not mental. The pupil who looks at the mouth (not the eyes) of his teacher learns pronunciation from the lip movements seen. Children while still young may learn to imitate the planned free manual exercises of the teacher and to move their fingers, hands, and bodies usefully, in a manner trained or coördinated by practice, so as to bring them into harmony with the later requirements of advancing education. All this requires knowledge and thoughtful labour on the part of the teachers, but is easily acquired by young pupils, in whom such method produces faculty for attention, control, retentiveness, and useful experience.

Muscular sense trained in the performance of free hand exercises may be followed by experience in feeling graduated weights and size; then by the appreciation of weight and dimensions their comparison, proportions, and description. Colours should be seen separately, their names taught and subsequently associated with the colours. Feelings of number and weight and the sense of time may be taught by planned experience; then the numerals and, later, methods of comparison are understood by the association of previous experiences.

Impressions are more useful and better retained when produced one at a time; they must subsequently be associated in like classes in a mental exercise of comparison. Weight may logically be compared with weight, size with size, colour with colour, and when standards of comparison have been learned, correct inferences may be formed; without such care in teaching, mental confusion results in the pupil and leads to fatigue. In the pupil's brain, words are impressions produced by sound, or by sight when written; their meaning arises from association with the child's experiences. Words may become connected without meaning, such as the letters of the alphabet and the numerals, &c. Education conducted stage by stage, always planned so as to implant in the pupil's brain experiences to be subsequently used, gradually builds up without confusion or waste of energy the power to appreciate agreement and difference of mental impressions with comparison of the degree (quantity, number) and the time (duration or order of succession) of impressions gained by experience. As teaching proceeds mental guidance must be afforded to the pupil by certain terms of instruction; he must learn what is wanted of him when told to repeat what he has learnt; to add or to subtract figures, or as more complex and advanced to compare a buttercup with a daisy or one triangle with another. The early training suggested will do much to make him receptive of the mental methods required in advanced instruction. Happily most children are naturally quick enough to pick up some knowledge and mental ability under any teaching; but if the method of procedure be carefully graded and planned for sequential employment, I think it will be found that their advance is more rapid and sure, happier to themselves, and attended with little fatigue and misunderstanding. The method and consecutive order in teaching have much to do with the ease and rapidity of mental evolution as well as avoidance of mental confusion which is inimical to mental healthiness

The observation of children and of their signs of brain action illustrates principles of wide application in mental hygiene and education, and affords a scientific basis for studying their mental abilities and faults. Early training of the natural characters of brain action by physical exercises prepares the way for the systematic cultivation of healthy mental action, and during the whole period of education the teacher's observation of the external evidence of mental status in the pupil will afford useful indications of the action and interaction of training and knowledge. Two examples may be given in illustration. Spontaneity of brain function is evidenced by movements seen in the face, the eyes, and the fingers; this is usually accompanied by analogous mental action. If this is well under control thoughts arising may easily be connected under guidance, while original thoughts are expressed. Mental spontaneity aids in recalling a fact or word forgotten; its failure is one cause of lessened memory and may be accompanied by the signs of fatigue. If spontaneity is not coordinated a crowd of thoughts arising leads to confusion and exhaustion. A spreading area of activity in the brain is seen in the display of emotion and mental excitement; if the increasing action is coördinated by direction, intensity of mental application may result, the greater activity raising some thoughts previously associated; on the other hand, if not guided, irregular mental action and exhaustion result.

There are many recognisable groups of children whose educational requirements differ and sometimes necessitate great discernment to assure that their respective needs are duly provided for. Nervous children may be recognised by a large amount of spontaneity, with a lively face, much movement of the eyes and fingers, the general balance of the body being asymmetrical, the head not held erect, and they are talkative The hands when held out balance in what has been described as the "nervous posture." These children are gregarious in social disposition, quick-witted, encouraging one another in frivolity. Such pupils need careful training to prevent emotional excitement and the tendency to hysteria; physical exercises in imitation of their well-trained teacher are useful. Defective children are now happily provided for in our schools. Their training presents interesting problems; all require the elementary teaching that has been described.

The social and economic value of mental hygiene may be illustrated by some results of investigation as to the physical and mental conditions of 100,000 children seen in schools. Time will only allow of a brief summary. Girls of school age are more numerous than boys, but their average school attendance is lower. Boys present a higher average number of dull pupils, and a higher proportion below normal development of body with brain-disorderliness. The proportion of girls who are delicate is higher than with boys, but among children of normal development the proportion of delicate ones is about equal. One-third of the dull pupils present signs of listlessness, lounging, inertness, which are largely removeable by attention to physical exercises and movements. The want of good training is a more general cause of mental dulness than congenital deficiency. In schools where physical training is well carried out the proportion of dull pupils is lessened.

The study of children and their requirements may draw together those who differ on many educational points and afford a basis for wise and united efforts in national education. I trust it has been shown that mental hygiene is a department of scientific knowledge based upon physiology, and that observation of children possesses a practical value entitling its inclusion in a scheme of university teaching.

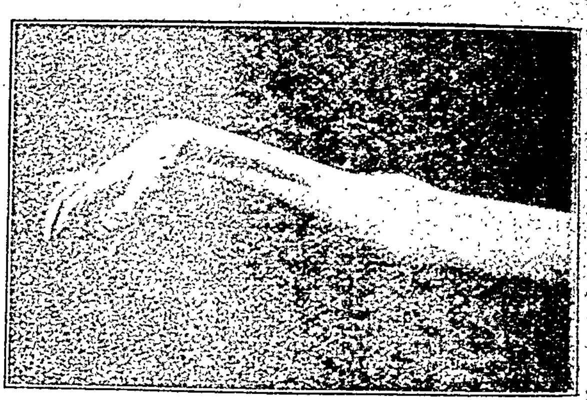
# VOLKMANN'S CONTRACTURE.

By LEONARD S. DUDGEON, M.R.C.S. ENG., M.R.C.P. LOND.,
ASSISTANT IN THE ELECTRICAL DEPARTMENT, ST. THOMAS'S HOSPITAL.

THIS deformity, which was first described by Professor Richard Volkmann[1] in 1875, has since received little attention from the medical profession in this country. There is little to be found on the subject in books on surgery (either past or present) or on deformities, or, in fact, anywhere in the literature, except in a few scattered papers of which those by Page, Littlewood, and Barnard are the best; full reference will be given to these papers later. This form of contracture is said to be rare. This statement, I think, is incorrect; it is far more probable that it is only rare in the sense that there is a scarcity of literature on the subject. I have considered it best to give first the four cases which have come under my own notice and which are recorded here for the first time; secondly, to give a summary of all the cases in the literature as far as it has been possible to do so; and, finally, to discuss the deformity at length.

CASE 1.—The patient, a child, aged five years, was admitted into St. Thomas's Hospital under the care of Mr. H. H. Clutton on Sept. 15th, 1897. At Christmas, 1896, she had fallen downstairs and had broken her right arm just above the elbow-joint. She was taken at once to a medical man, by whom the fracture was set and the arm was put up in splints. According to the relatives there was no trace of a wound when the arm was first seen. Two days later they called in another medical man who took the splints off and found that there was a considerable wound over the seat of the fracture and a great deal of inflammation present, while the fingers were swollen and discoloured. The arm was dressed but the splints were not reapplied. Wasting and contracture seem to have set in during the process of healing, which appears to have been very slow and not finally completed until about six months after the original accident. On admission into St. Thomas's Hospital the condition was noted as follows: "The whole right arm is wasted, the forearm especially, consisting of little more than skin and bone. It is held pronated midway between pronation and supination and slightly flexed on the arm. The hand is flexed at right angles to the forearm; the fingers and thumb are slightly flexed on the palm. Extending right across the elbow-joint is a large scar which has produced considerable contraction in the surrounding skin. At the inner end of this scar begins an abnormal bony prominence on the inner edge of the humerus, half an inch above the front of the internal condyle which appears to be in the normal position. A sharp ridge runs upwards from this bony point which is just beneath the skin. Complete flexion of the forearm is prevented by this bony prominence. Movements of pronation and supination cannot be performed actively and only to a slight extent passively. The head of the radius appears to be in the normal position, likewise the head of the ulna. The hand cannot be moved voluntarily. The interossei act fairly well. The fingers are flexed on the palm. Sensation of hand and forearm is normal; the hand cannot be extended." Dr. H. G. Turney, physician to the electrical department, reported that the electrical reactions were normal. The diagnosis of ischæmic myositis was made. The treatment adopted was massage twice daily. On Oct. 15th the following note was made: "There is some improvement of the movement of the fingers, otherwise the condition practically remains unchanged, despite the massage twice daily." The patient left the hospital on Oct. 25th, 1897. On Nov. 22nd, 1901 the child was brought up to St. Thomas's Hospital at my request (Fig. 1). The forearm was extremely wasted, more so if possible than before, except at the upper end of the forearm, where the muscles were more bulky and firm and hard. The forearm, which w  strongly pronated, was considerably shorter than its fellow, and the bones—i.e., the radius and the ulna—were much smaller in every way. The hand was flexed and could not be extended, neither could pronation or supination be performed, while the fingers were more pliable than they usually are in such cases, being able to perform all movements to a certain extent. The inter-phalangeal joints were flexed, but on full flexion of the wrist they could be completely extended. The hand was cold and blue, but sensation was absolutely normal. There were no trophic changes of the skin or nails, &c. The finger-joints were quite normal. There was a well-marked prominent boss at the back of the wrist-joint. There was a large scar at the upper part of the forearm, showing the site of a past extensive pressure sore. All movements of the elbow-joint were perfect. Electrical reactions to both nerves and muscles were normal; it was surprising to see such atrophied muscles contract so sharply and so strongly. Both Mr. Clutton and Dr. Turney who saw the patient considered the case to be the worst one that they had ever seen. When the child left St. Thomas's Hospital in 1897 the parents were told to try massage. When I inquired of the child's father to what extent he had carried out the instructions his answer was: "As I found no improvement after three weeks' massage I gave it up as useless." I think that I can therefore state that the patient received practically no treatment, hence this disastrous result.

FIG. 1.



Showing condition of hand and forearm in Case 1 on Nov. 22nd, 1901

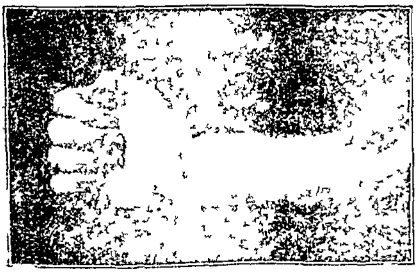
CASE 2.—The patient, a man, aged 20 years, was admitted under the care of Mr. Bernard Pitts into St. Thomas's Hospital on April 13th, 1898. He gave the following history. On June 18th, 1897, he sustained an injury to his forearm by means of a sledge-hammer; he was seen by two medical men at the time of the accident and five weeks later in the out-patient department at a "general hospital." The diagnosis of the injury was different in each case—(1) bad sprain, (2) dislocation of the wrist, and (3) fracture of the lower end of the radius and ulna. The practitioner who attended him at the time of his accident bandaged the forearm and hand on an anterior splint which reached the tip of the fingers. There was a good deal of swelling when the splint was applied. There was no discolouration of the fingers and only slight pain occurred. Five weeks later he went to the hospital. The splint was removed, there was no contracture now, and the arm was put in plaster for more than two months. (It will be noticed that contraction would be impossible if the splint reached to the tips of the fingers, but that it occurred as soon as the plaster splint was applied, as this reached only to the wrist-joint.) At the end of that time massage was applied and passive movements were practised. Contraction of the fingers on the palm of the hand was well marked two months after the accident. As an operation was advised at the hospital he left that institution and came to St. Thomas's Hospital. The left arm was now much wasted and the patient held the wrist flexed and likewise the fingers; all movements were considerably diminished. There was no scar on the forearm or hand which might show the site of a past pressure sore. There was no report on the electrical reactions. The treatment adopted was massage and faradic current daily. The patient left the hospital on April 27th, 1898. On Nov. 7th, 1901, I saw him in the electrical department at St. Thomas's Hospital. He told me that for over a year after he left the hospital he had had massage and passive movements for "some time" each day. The contraction very gradually improved and he could extend the fingers slightly at first and more so as time advanced; there was now no contraction; the fingers were held in the position of semi-flexion, but the movement of extension was perfectly good. The wrist movements were normal. The forearm was slightly smaller and shorter than on the opposite side and the muscles seemed to be firm to the touch. The power was not quite so good as on the opposite side. Sensation was absolutely normal. The electrical reactions which I took myself were normal, both nerves and muscles. The circulation in the hand was good and the skin was quite normal. The patient worked now as a watchman and could do his work, or any other, perfectly well.

CASE 3.—A child, aged five years, was admitted to St. Thomas's Hospital on June 25th, 1898, under the care of Mr. Pitts. On April 20th, 1898, he had fallen down and fractured his right arm. When seen in the casualty department of the above hospital it was found that there was a greenstick fracture of the right ulna and radius at the junction of the middle and upper thirds. This was set and put up on anterior and posterior splints. He was seen again in a week (April 27th), when the splints were removed and the arm appeared to be progressing satisfactorily; the splints were re-applied, and the patient was seen again on May 3rd, when the arm was in good condition and the splints were again re-applied until May 9th. During this last week the boy's mother noticed the fingers to be slightly swollen. On removal of the splints a sore was found on the flexor surface of the forearm; this was dressed and the splints were re-applied. On

May 25th the wound was almost healed but the fingers were flexed and the wrist was slightly contracted. Passive movements massage and the galvanic battery were given every other day but the contracture did not improve. On admission into the hospital he seemed to be a healthy looking boy with contraction of the hand. The wrist was partially flexed and the fingers—i.e., the two terminal phalanges—were strongly flexed and could only be extended on full flexion of the wrist. The wrist and fingers could not be extended at one and the same time. There was no loss of power of extension of the wrist. The electrical reactions were normal. The treatment adopted was massage twice daily. On August 15th there was considerable improvement in the affected arm, the tendons were not so tense and the wrist joint was moved with more freedom. The patient left the hospital on August 6th 1898. At my request the child came to see me in the electrical department on Nov. 14th 1901. Over three years had elapsed since the accident. There was now absolutely no deformity of the hand and the position of the fingers was normal. There were very slight weakness and wasting of the forearm muscles which were firm and hard. The scar of the old pressure sore was a prominent landmark about the middle of the forearm. Sensation was normal and the electrical reactions were also normal. The mother to whom the recovery was chiefly due told me that she had persistently and right up to the time of my seeing the patient carefully rubbed his arm night and morning. He had also been taught to manipulate the mangle and as soon as he could do so to wring out washing; in fact every movement that was of any service was employed. The boy was taught to bend his fingers backwards whenever he could and it was done for him every night and morning after the massage. The deformity very gradually disappeared—in fact it was only during the last three months—i.e. since August 1901—that there had been noticed complete absence of any deformity. The patient was now able to do ordinary work as well as any one of his own age.

CASE 4.—The patient a child aged four years was an out patient at St Thomas's Hospital. On Dec. 6th 1900 she had broken her right upper arm just above the elbow. There was a good deal of swelling at the time. She came to the casualty department where the arm was put up in a flexed position in plaster splints. On the next day the fingers were swollen and were according to the child's mother dark in colour but this fact was absolutely disregarded by the parents. The patient was not brought to the hospital till the fourth day after the application of the splints. There had been no pain and I suppose that this must have been the reason for such delay. When the splints were removed there was found a large pressure sore on the flexor surface of the forearm at the upper part and contraction of the fingers had commenced. The arm was dressed and only lightly bandaged. On Jan. 17th 1901 I saw her in the electrical department at St. Thomas's Hospital where she has continued ever since under the care of Dr Turney. At that time the following notes of her condition were taken: "The elbow joint is fixed and in a semi flexed position. The forearm is held pronated and the muscles are much wasted and seem very firm to the touch. There is strong contraction of the second and third phalanges into the palm of the hand with extension of the first phalanges. The wrist is semi flexed and the fingers cannot be extended except on full flexion of the wrist. The wrist and fingers cannot be extended at one and the same time. The action of the interossei is fairly good. The hand is cold and sensation is normal. There is a scar on the ulnar side of the forearm on the flexor aspect at its upper part showing the site of the past pressure sore. The electrical reactions are absolutely normal except in those muscles supplied by the ulnar nerve in the forearm and hand which show diminished faradic and galvanic irritability. The nerve also shows diminished reaction to the faradic current. The finger joints are unaffected. There is well marked thickening of the internal and lower end of the humerus and this I think limits movements of the forearm on the arm. Dr Turney examined the case and diagnosed it as ischæmic myositis; he also found the electrical reactions as above. Massage was ordered by Dr Turney and was carried out three days a week for 15 minutes at each visit, by a competent nurse the mother doing the massage as directed in the intervals of her visit to the hospital. The condition has shown some improvement but the contraction is quite typical. It is now 10 months after the accident and both flexion and extension of the forearm can be well carried out also pronation and supination but to a much less degree. The hand is still in the same position but the movement of the fingers is better. Passive extension of the fingers causes the child a good deal of pain but not nearly so much as it did. Sensation is normal. Skin normal. No trophic lesions. Electrical reactions quite normal even in the ulnar distribution so it is likely that the partial loss before was due to splint pressure. The circumference of the forearm is markedly diminished as compared with the sound side and there is obvious shortening. Treatment is carried out exactly the same as before."

FIG. 2



Condition of hand in Case 4 on Jan. 17th, 1901.

The illustration (Fig. 2), for which I am indebted to Mr Grimwade, shows the absolutely typical condition of the contraction. I know also of three other cases, but these I am unable to record owing to the fact that I cannot obtain full notes of them.

The following is a brief account of all the cases the literature of which I have been able to obtain.

CASE 5.—A boy aged eight years came under the care of Mr Raymond Johnson with extreme contraction of the wrist and fingers following fracture of the lower extremity of the humerus.[2] The case had been treated by means of wooden splints which as a result of undue pressure had produced a sore on the front of the arm. The length of time between the fracture and the subsequent deformity of the wrist and fingers was not stated. Some slight degree of contractility still remained in the affected muscles—i.e., the flexors of the fingers. An exploratory operation had shown that there was no abnormal condition of the nerves at the seat of the fracture. A diagnosis was therefore made of Volkmann's "ischæmic paralysis." In order to relax the contracted tendons a short piece of bone was excised from the middle of the shaft of the radius of the ulna. The effect on the contracted wrist and fingers was satisfactory but unfortunately the divided bones were repaired only by fibrous tissue and a leather splint was necessary to give strength to the arm.

At the discussion at the meeting of the Harveian Society after the reading of this case Mr Edmund Owen said that he had met with three cases of this sort, all in children. He described one in which the forearm had been fractured in its upper part with subsequent ischæmic myositis. He had cut down on the median nerve and had found it healthy, but the flexor muscles were in a state of fibrous degeneration. Division of the contracted tendons had produced an unsatisfactory result.

CASE 6.—A girl aged six years was admitted to Guy's Hospital under the care of the late Mr J. N. C. Davies Colley[3] on May 18th 1898. The child had fallen out of a cart and had broken her right arm in 1896. The medical man who attended the case is reported to have said that there were three fractures about the elbow joint and that the humerus was split longitudinally to about the middle of the shaft where there was a transverse fracture. The arm was set and it got quite well except for a lump which formed just above the elbow and prevented the child flexing her arm. This lump together with a ridge which formed along the line of the splint was removed by Mr Pollock on the December after the accident with a good result. The power of flexion of the forearm returned. (Owing to the death of Mr Pollock the case came under the care of Mr Davies Colley.) The condition of the patient was reported to be as follows: Elbow very prominent otherwise normal; wrist is flexed at a right angle; metacarpo-phalangeal joints are extended; the inter phalangeal joints are flexed. Extension of forearm is perfect while there is no power to extend the wrist and very slight power to extend the phalangeal joints. The forearm is pronated with great limitation of pronation and supination. Sensation normal. Slightly above the level of the elbow joint is a T-shaped scar and on pressure in this area a few small tender nodules are felt. The flexor muscles of the forearm are wasted and hard. There is no evidence of any nerve palsy. There has been a pressure sore in this case which is shown now by induration of the skin and muscles which are wasted. The treatment adopted was as follows. A three inch incision was made in front of the forearm just below the elbow joint. The muscles which were much wasted and were formed chiefly of fibrous tissue which was also intimately connected with the median and ulnar nerves which were rather swollen were otherwise healthy. The affected muscles—viz. the flexor sublimis flexor carpi ulnaris palmaris longus flexor carpi radialis pronator teres and the flexor profundus—were partly cut and partly torn through. Vigorous efforts were made to straighten the wrists and fingers which succeeded as regards the wrist but not the fingers. The result of the operation was perfect extension of the wrist but all attempts to extend the fingers were useless. One month after the first operation a second was performed. An incision was made just above the wrist line, the tendons of the flexor sublimis, flexor profundus and the flexor longus pollicis were cut through, the fingers and thumb were completely relaxed. The arm and hand were put in position on a splint with the fingers and wrist fully extended. Three months after this operation the fingers were in a good position and had good movement except for flexion which was of course, absent.

Mr Davies Colley, in the same paper, also narrates a case of myositis in the calf muscles, that of a boy with very bad *talipes equinus* so that the toes were pulled down so much that they looked like "claws." Two years previously he had sustained a compound fracture of the tibia and fibula, the calf muscles being injured. The parts healed after long suppuration. Mr Davies Colley had divided the tendo Achillis, all the tendons behind the malleoli and the flexor longus hallucis, so that the boy had his toes and foot in good position.

CASE 7.—A boy aged six years who was sent to Mr J. Jackson Clarke,[4] gave the following history. Six weeks previously he had sustained a fracture of the lower end of the humerus which had been put in splints and had re-set three days later. There had been much swelling of the elbow joint and for the first two or three weeks the boy screamed if his fingers were touched and was incapable of moving them. The swelling about the joint subsided in five weeks but left it immobile from adhesions which were afterwards broken down under chloroform. When Mr Clarke first examined the patient there was no reaction in any of the muscles of the forearm to either the galvanic or faradic current, but after a week's treatment with galvanism and massage slight reaction was noticed, which was followed by some reaction in some of the flexors of the wrist, but the flexor sublimis digitorum, pronator teres, and pronator quadratus never reacted at all, but the supernator longus always reacted. Sensation returned coincidently with the partial return of muscular reaction. Under this treatment the boy got back considerable power in the forearm, but the thumb muscles were very obstinate. For some weeks he had fair use of the arm and hand, but the whole arm then began to waste, stiffen, and become much more pronated. Sensation was perfect. Clawing of the hand began four months after the original accident, and it increased in spite of massage. As soon as the deformity had ceased to increase Mr. Clarke *divided the flexor tendons above the wrist. This operation* removed the whole deformity.

CASE 8.—A boy, aged four and a half years, was admitted into St. Mary's Hospital on Nov. 5th, 1898, under the care of Mr. H. W. Page.[5] In the preceding month he had fallen on his left elbow and had sustained a transverse fracture of the humerus. (Separation of the lower epiphysis was not excluded.) The treatment adopted at the time of the accident was anterior and posterior splints to the forearm, with the limb put up in a flexed position. All seemed well the next day, but when the child was brought to the casualty-room a few days later there was found to be total loss of power in the fingers and wrist. There was a superficial slough immediately below the bend of the elbow caused by splint pressure; this became detached in about four weeks, and left an open wound which healed by granulation. The treatment employed at the second visit to the hospital was a single posterior splint, which was, however, abandoned at the end of four weeks, and the parents were instructed to manipulate and rub the arm, *for an increasing tendency to contraction* of the fingers had been noticed, and the wrist was also becoming more and more flexed. The attempt at reduction under an anæsthetic was fruitless. Mr. Page first saw the patient three months after the accident; the child's arm was then described as follows: "It is flexed and in a position midway between pronation and supination. There is extreme flexion of the wrist and the fingers are flexed on to the palm. The old scar is tender, so is the forearm. The joints are clearly unaffected. Extension of wrist and finger is hardly possible even with force. There is partial anæsthesia, only involving the ulnar distribution of the hand, and some wasting of the first dorsal interosseous muscle. The flexor muscles seem firmer than usual. No injury can be detected to the median, musculo-spiral, or ulnar nerves, except that previously mentioned. My own belief is that there had been a separation of the lower epiphysis of the humerus. Contraction is not lessened under an anæsthetic." Massage, electricity, and passive *movement* were all found to be useless. On Dec. 20th, 1898, Mr. Page operated. An incision was made just above the wrist line, and the tendons were lengthened in the usual way. The muscles gave the impression of being stiff and unyielding, firmer than natural, and as if their structure had been changed. The hand and arm were secured after the operation in the flexed position. The parts healed by first intention. At the end of 14 days gradual passive movements of the forearm, the hand, and the fingers took place. Massage and electricity were added. The patient left the hospital in February, 1899, with very slow improvement. He then attended the out-patient department for electrical treatment, under the care of Dr. Wilfred J. Harris, who stated that there was at first very decided reaction of degeneration in the affected muscles; recently the condition was not so marked. In July, 1899, Mr. Page next saw the child. There was now distinct improvement. The forefinger tendons had not united, otherwise all had. By October, 1899, great progress had taken place. All the tenderness had gone, the forearm could be completely extended, and the wrist and the hand could be voluntarily put in the extended position. Flexion of the fingers was easily performed and the child could "make a fist." In the forefinger the flexor profundus alone acted upon it. The muscles of the forearm had lost that peculiar sense of resistance so characteristic of them.

CASE 9.—A girl, aged eight years, was admitted into the Leeds Infirmary under the care of Mr. H. Littlewood[6] on Nov. 17th, 1898. Four months before admission she had a fracture separation of the lower end of the humerus, with a good deal of swelling of the parts. The arm was put up in an internal rectangular splint for five weeks. When the splint was *removed* it was noticed that the fingers were contracted and the contraction gradually increased. There was some limitation of the movements of the elbow-joint; it could be flexed to about a right angle, but could not be completely extended; flexion was limited by a bony prominence at the inner side of the lower end of the humerus. Extension of fingers was impossible except when the wrist was flexed and then it could be easily accomplished, otherwise the fingers were contracted into the palm of the hand. There was no sign of any past pressure sore. There was a lump in the upper third of the forearm on the flexor aspect, situated in the muscles. There was some loss of sensation in the ring finger and in the little finger. An operation was performed on Dec. 5th. All the flexor tendons were lengthened about an inch; the fingers and wrist were extended. A firm thick pad of antiseptic wool was applied from the finger tips to the elbow. The wound healed by first intention. After leaving off the dressing for a few days it was found that there was a tendency to contraction of the sutured tendons. To prevent this the limb was massaged and a back splint was worn for two or three hours every day. The patient's condition so improved before leaving the infirmary that she could do some knitting. The parents had persevered with the rubbing and the child had a very useful hand as the result.

CASE 10.—A girl, aged six years, was admitted under the care of Mr. Littlewood[7] into the Leeds Infirmary on Jan. 7th, 1899. In May, 1898, she had fallen from a ladder and had sustained a severe fracture about the left elbow-joint, also of both bones of the forearm. There was considerable swelling of the parts and the fractures were with difficulty kept in position. A splint sore formed about the middle of the back of the forearm. Contraction of the fingers was very marked so that in flexion of the wrist the fingers could not be fully extended. Eight months had elapsed since the time of the accident. Both fractures had united and movement of the elbow-joint was good. A lump in the flexor muscles of the forearm was well marked. The operation was performed on Jan. 9th, 1899. All the tendons except the flexor carpal ulnaris were divided, lengthened about an inch, and sutured. Similar dressings were used as in Case 9. The wound healed by first intention. Daily massage was employed and the patient left the infirmary on March 14th, 1899. The fingers were then quite straight and she had some power of flexion. When the case was reported the condition of the implicated parts was greatly improved and the attainment of a very good result appeared probable. On exposing the nerves they were found to be healthy, in both this case and in the preceding case (Case 9).

CASE 11.—A girl, aged three years, was admitted into the Metropolitan Hospital on May 2nd, 1900, under the care of Mr. H. L. Barnard,[8] with the following history. On March 16th, 1900, she broke both bones of the right forearm about the middle; anterior and posterior splints were applied. She was seen on the next day; there was no pain. When the splints were readjusted at the end of the week a pressure sore was found extending about three inches from the middle of the front of the forearm to the front of the wrist, whilst a smaller sore was found at the back of the forearm in its lower part, and a still smaller one upon the thenar eminence. The sores rapidly healed, as did the fracture also. No note was taken at the time whether the child moved her fingers or not. About the middle of April the fingers and the top joint of the thumb began slowly to flex, and this flexion steadily progressed in spite of massage and the restraint of a splint. The position of the hand on admission into the hospital was that of *main-en griffe*. When the wrist was extended the fingers were extended at the metacarpo-phalangeal joints and flexed at the inter-phalangeal joints. The last phalanx of the thumb was fully flexed. When the wrist was completely flexed the fingers could be extended. There was no definite anæsthesia. Voluntary movements of the hand and the wrist were practically lost. On June 27th a chronic whitlow was seen on the tip of the right index-finger. On Dec. 10th Mr. Barnard operated. The four tendons of the flexor sublimis, the tendon of the flexor longus pollicis, and six strands of the flexor profundus were lengthened in the usual way and the tendons were sutured. Although no tourniquet was applied *there was very little bleeding; the wound was very dry*. The muscles exposed were pale, firm, fibrous, and dry, very unlike the muscles of children. The arm was put on a splint with the fingers fully *extended. The wound healed by first intention. The after-*treatment adopted was massage and passive movements every other day. They were begun 14 days after the operation. The child wore a back-splint at night, as there were signs of further contraction. During the day the sound arm was tied to the side so as to give the injured arm plenty of movements when the child was playing with her toys.

CASE 12.—A little boy, aged four years, was admitted into the Metropolitan Hospital on May 12th, 1900, under the care of Mr. Barnard. On March 15th the patient had crushed the upper part of his left forearm, producing extensive swelling from effusion of blood; fracture was excluded by the x rays. The arm was placed on an external angular splint and was only lightly bandaged as it was very painful. About five weeks later contraction of all the flexor tendons commenced, and when seen by Mr. Barnard his hand was in the condition of *main-en-griffe*. The usual wrist sign was present. The forearm was fully pronated and fixed. There was no definite anæsthesia of the hand, although the skin of the digits was smooth and glossy and the whole hand was much colder than its fellow. Patient and persistent massage and passive movements all produced no improvement—in fact, the contraction increased. On May 30th Mr. Barnard operated, splitting the tendons of the flexor sublimis, the flexor profundus, and the flexor longus pollicis as before and then suturing them. Absence of hæmorrhage and dryness of the wound were nearly as marked as in Case 11. The parts healed by first intention. The same treatment was adopted as was used in the last case. A chronic, painless whitlow appeared on the index finger. Improvement was very marked after four months' treatment. As the hand was still pronated Mr. Barnard operated again on Oct. 20th. The pronator quadratus was separated from its ulnar attachment, then the forearm was readily supinated and fixed in this position on a splint. The after-treatment consisted of a splint at night, passive movements, and massage every day. There was very fair rotation of the forearm. In this case and in Case 11 the *patients were progressing favourably at the time that this* paper was written. The electrical reactions of the muscles of the forearm in this case were made by Dr. W. S. Hedley lately, who stated that he obtained a reaction of degeneration.

CASE 13.—The patient, a female, aged 20 years, came under the care of Mr. F. C. Wallis,[10] at Charing Cross Hospital in July, 1900, with the rare deformity of congenital absence of the superior radio-ulnar articulation in both forearms. The right forearm was capable of some degree of supination, but in the left it was impossible to obtain any such movement. In consequence the girl was unable to earn her living. Mr Wallis operated at the earnest desire of the patient and her friends on July 6th, 1900. The operation took one and a quarter hours, and during this time an Esmarch's bandage was kept round the upper arm. The radius was divided close to the head and the arm was forcibly supinated; in doing this the ulna was fractured in its lower third. The wound was closed and the arm was fixed in splints. 24 hours later the arm, which was much swollen, was red and covered in places with large bullæ. Paralysis and loss of sensation seemed complete and the general temperature was raised. The splints were immediately removed and some stitches were taken out to relieve tension and the *arm* was redressed. There was *no suppuration* gradually the swelling diminished, but the paralysis continued, and the fingers assumed the position of *main-en-griffe*. 10 days after the operation it was found that the anæsthesia of the forearm and hand was confined chiefly to the ulnar and median distribution. Passive movements were now daily performed and galvanism was applied, but the ends of the fractured ulna were unable to unite owing to these movements. Three months after the operation Mr. Wallis wired the fractured bone with good result. The condition of the hand and forearm after the ulna had united was reported to be as follows: "With the wrist extended the second and third phalanges are flexed on the palm; with the wrist flexed the fingers can be extended; the thumb is practically useless and the muscles of the hand are much wasted. Loss of sensation as before." For the next seven months the hand and forearm were daily galvanised and faradised, and a hot air bath was used. Massage was daily performed and on three separate occasions the wrist and fingers were manipulated under gas. This treatment at first gave good results; the muscles of the upper part of the forearm improved, the fingers could be easily extended, and a certain amount of active movement was restored to the fingers and thumb. The wrist was more pliable and sensation was much improved. The skin was normal This was the condition of the patient's arm nearly 12 months after the original operation. A second operation was now performed. The tendons of the flexor sublimis, the flexor profundus, and the flexor carpi radialis were divided and lengthened in the usual way The tendon sheaths on being opened were found to be much thickened and more vascular than usual The median nerve was found to be surrounded by fibrous tissue which was adherent to the nerve sheath The muscles exposed were pale in colour and their fibres were to a great extent replaced by fibrous tissue The wound was closed and the hand was placed on a back splint with the fingers extended Passive movements were commenced at the end of a fortnight and active movements in the middle of the third week Galvanism and massage were also applied The report proceeds The present condition of the hand is one of improvement Sensation has completely returned over the distribution of the radial nerve and partially over the median but the ulnar shows little progress After massage the fingers are quite supple and the range of movement is much increased She can also use the hand extremely well for needle-work "

CASE 14 —A youth aged 18 years was shown by Professor Schloffer[11] at the Association of German doctors in Prague The patient was brought to the clinic on Oct 19th 1900 having shot himself with a revolver in the region of the heart The bullet entered at the level of the fifth rib at the midsternum No exit wound was found and no projectile could be felt under the skin The patient was collapsed On examination the heart dulness was found to be normal the right radial pulse could not be felt and the left was very weak rate 100 The patient slowly improved in bed In the next four hours the action of the heart becoming stronger On the following day there was severe pain in the right arm and the right radial pulse could not be felt the left pulse was good and fairly strong the movement of the right elbow joint was normal and the right hand and finger joints were immoveable except for a slight amount of extension of the hand The muscles of the right forearm were swollen hard and very tender on pressure The skin of the forearm and hand was cyanotic Passive movement of the fingers caused severe pain in the forearm Sensation was intact in the upper arm, but was very much diminished below the elbow joint in the region of the median ulnar and musculo spiral nerves Professor Schloffer diagnosed ischæmic paralysis On examining for the projectile in the depths of the right axilla in the region of the axillary artery there was a hard sense of resistance which was thought to be the projectile and this was confirmed by the Röntgen rays This had produced closure of the axillary artery probably from thrombosis and had led to such an extraordinarily rare result as ischæmic paralysis A little later there was dulness at the base of the right lung behind, with a temperature of 39 5° C , both these signs finally disappeared The local condition improved greatly under very energetic massage so that the power of movement greatly returned , but at the time that the case was reported the right forearm was markedly atrophic when compared with the left side The muscles felt hard and firm In some places hard nodules could be felt Dr Margalie found the reaction of degeneration in the affected muscles Sensation had on the whole become a little better, especially in the forearm but in the hand it was still diminished to all three nerves and in the fingers sensation was almost absent The treatment adopted had been hot air baths but these caused severe blisters on the third and fourth fingers without the patient being aware of the fact No effort was made to remove the bullet Professor Friedel Pick in the discussion which followed remarked that this case was noteworthy owing to the change in sensation for judging from the literature the rule in ischæmic paralysis was that motor paralysis lasted for a long time but sensation was rapidly recovered

CASE 15 —The patient a boy aged 12 years was admitted to St Thomas's Hospital under the care of Mr W H Battle[12] on Dec 2nd 1895 and remained under treatment until Feb 14th, 1896 , since then he has been in the out patient department till June of this year The history of the case is as follows The boy broke his forearm on May 21st 1895 Six weeks after the fracture he could not put his fingers straight The fracture had been treated by means of anterior and posterior splints which had produced a pressure sore in the middle of the forearm under the anterior splint The left arm was wasted and the forearm was held pronated with the fingers flexed When the wrist was flexed the fingers could be extended , this however could not take place with the wrist extended There was marked wasting of the hand muscles A scar was present over the front of the forearm showing the site of the past pressure sore Sensation was normal The electrical reactions were normal No lengthening of the flexors could be brought about under an anæsthetic The muscles were very rigid The treatment adopted was rubbing galvanic current, and gymnastic exercise and there was some improvement

*Definition* —A contraction of the fingers and sometimes of the wrist which comes on rapidly with loss of power which is not absolute in the forearm muscles after a severe injury, usually in the region of *the elbow joint, generally* in young children The deformity is due to changes in the flexor muscles without injury to the peripheral nerves caused in many cases by tight bandaging and the pressure of splints

I next come to discuss the deformity from its different standpoints

*Etiology* —By the following tables (Tables I and II ) which I have made of my own cases and of *those* of the literature the chief causative influences can be seen at a glance

In Table II pressure sore occurred in six out of a possible 11 cases In one of the six cases there were three pressure sores , of the remaining five cases it did not occur in three, in one it is not stated whether it did or did not, and in the last case bullæ were present instead In Table I , out of four cases pressure *sore occurred* in three and was absent in one From this it is easy to see how common a factor it is I do not think it causes the contracture, for it is generally limited to one part of the forearm, not over an extensive area, nor does it usually extend down deeply into the soft tissues , therefore it is hard to understand why it should cause such contraction of all the forearm muscles , but I do think it is a sign of great importance, as it does show to what pressure the parts have been subjected There is usually a good deal of swelling, which has been treated by tight bandaging and splints , with such great resistance the skin is nearly bound to slough The late Mr Davies Colley,[13] on the other hand, believed that "pressure sore" was a cause of the contracture, but it is obvious if it is in some cases that it cannot be in all Splint pressure is claimed by many as the "cause" Mr Littlewood[14] disagrees with this statement and his argument is backed up by the fact that it is clearly shown by looking at Table II that there was no splint pressure in certainly *three* cases out of the 11, and possibly more It is far more likely that it is a combination of large effusion into the soft parts and splint pressure, but that it does occur without any splint pressure I have already stated Mr Page thinks that the contracture is caused by a combination of pressure, fixation and ischæmia Other causes are Esmarch's bandage (Case 13 shows this fact very well and Volkmann[15] states "I have never seen a case result from the use of Esmarch's bandage although it is known to be a cause") , when the main artery of a limb has been ruptured, ligatured, or contused , and lastly, the very interesting case (Case 14) published by *Professor Schloffer where it followed thrombosis* of the axillary artery , long continued and severe cold ,[16] rupture and severe contusion of the flexor muscles in young children (this fact will be dealt with in the pathology) , the suppuration of muscles , and finally, Mr Anderson summarises the etiology thus "It is a result of prolonged fixation of forearm fractures by any form of apparatus that intercepts the free circulation of blood through the muscles and nerves of the part "

*Symptoms* —These come on rapidly, as Volkmann describes, "in half a day or less in very severe cases" The great feature in the history of a case of this deformity is the onset of paralysis of a limb with contracture, this is most important and characteristic The fingers sometimes go blackish in colour and frequently swell There is rarely any pain , the absence of this symptom may be the cause of the splints not being loosened more rapidly, but on removal of the splints the *forearm* is *often* tender and *sometimes* extremely so There is often sloughing of the skin, usually in the middle or upper part of the flexor surface of the forearm The fingers are at first simply flexed, but soon pass into the position so characteristic of this deformity, which has been so ably described by Mr Littlewood Once this position is seen it is not *easily* forgotten , it has been present in every well marked case With the wrist extended the *metacarpo* phalangeal joints are extended also , the inter phalangeal joints of the fingers and the terminal joint of the thumb are, however, strongly flexed, so that the tips of the fingers touch the lower part of the palm, and no reasonable amount of force seems capable of straightening them , but as soon as the wrist joint is flexed to a right angle then the inter phalangeal *joints* can be *easily extended* *In* very bad cases the wrist becomes strongly flexed and is incapable of extension The hand is pronated and the forearm is generally semi flexed The flexor muscles of the forearm seem hard firm, and much wasted A thickening is sometimes felt in the soft tissues, usually in relation to the pressure sore which is so frequently present. A swelling bony in character, is sometimes to be found at the lower end of the humerus, generally at the inner side *Sensation may* be normal or there may be partial or complete anæsthesia , this is dependent on the condition of the peripheral nerves There are thus to be seen usually three grades of this deformity (1) partial contraction of the fingers , (2) the hand in the typical position , and (3) strong flexion of the wrist and fingers, without any power of extension There are no true trophic lesions in pure ischæmic myositis *but the hands are frequently cold and blue and the* skin smooth The fingers frequently swell when the arm hangs down by the side for some time It is said that the joints become ankylosed, similar to the ankylosis in traumatic arthritis, but I could find no such case in the literature or any mention of such a *condition having been recorded* , *in* those cases in which any reference was made to the joints *they* were always said to be normal In well marked cases there is as much *shortening* of *the* bones as *is* met with in acute anterior poliomyelitis &c How does this occur? Dr. Turney's explanation seems completely to explain such a result. He says "The growth of bones proceeds only *pari passu* with the amount of support it has to give to its attached muscles "

*Electrical reaction* —Dr Turney tells me that he considers

TABLE I.—CASES PUBLISHED FOR THE FIRST TIME.

| Cases. | Under the care of— | Nature of the accident. | Treatment adopted. | Remarks. |
|---|---|---|---|---|
| Case 1 | Mr. Clutton and Dr. Turney. | Fracture of the right arm just above the elbow-joint. | Splints, anterior and posterior. | A good deal of swelling of the soft parts and pressure sore |
| Case 2 | Mr. Pitts and Dr. *Turney.* | Some injury, cause uncertain. | Anterior splint to the forearm for five weeks; plaster-of-Paris for two months. | Well-marked swelling of the soft *parts. No pressure sore.* |
| Case 3 | Mr. Pitts and Dr. Turney. | Greenstick fracture of the right radius and ulna at the junction of the middle and upper thirds. | Anterior and posterior splints. | Pressure sore on flexion on the surface of the forearm. |
| Case 4 | Mr. Clutton and Dr. Turney. | Fracture of the lower end of the right humerus. | Plaster splints. | Well-marked swelling of the soft parts; pressure sore. |

TABLE II.—CASES FROM THE LITERATURE OF THE SUBJECT.

| Cases. | Under the care of— | Nature of the accident. | Treatment adopted. | Remarks. |
|---|---|---|---|---|
| Case 5 | Mr. Raymond Johnson. | Fracture of the lower end of the humerus. | Wooden splints. | No statement as to whether any swelling was present; pressure sore on the front part of the fore-arm. |
| Case 6 | Mr. Davies-Colley. | Severe fracture of bones "about the elbow-joint." | Not stated. | Considerable swelling of the soft parts and a pressure sore. |
| Case 7 | Mr. Jackson Clarke. | Fracture of the lower end of the humerus. | Splints. | Much swelling of the elbow-joint. |
| Case 8 | Mr. Page. | Transverse fracture of the lower *end of the humerus; separation* of the lower epiphysis. | Anterior and posterior splints to *the forearm (limb put up in* flexed position). | Pressure sore; presence of swell*ing of the soft parts, but stated.* |
| Case 9 | Mr. Littlewood. | Fracture separation of the lower end of the humerus. | Internal rectangular splint. | Marked swelling of the tissues; no pressure sore. |
| Case 10 | Mr. Littlewood. | Severe fracture of the lower end of the humerus, radius, and ulna. | Splint (kind of splint used not stated). | Considerable swelling of the soft parts; pressure sore. |
| Case 11 | Mr. Barnard | Fracture of the radius and ulna (about the *middle of the shaft).* | Anterior and posterior splints. | Large pressure sore on the fore-arm and two others of smaller size; presence of swelling not stated. |
| Case 12 | Mr. Barnard | Severe contusion of the upper part of the forearm; fracture excluded by the x rays. | External angular splint and very light bandaging. | Great swelling of the soft parts with bloody effusion; no pressure sore. |
| Case 13 | Mr. F. C. Wallis. | Esmarch's bandage to the upper arm for one and a quarter hours. | — | Much swelling and redness and the arm covered with bullæ. |
| Case 14 | Professor Schloffer. | Thrombosis of the right axillary artery. | — | The skin of the right forearm and hand swollen and slightly cyanotic; the muscles very tender. |
| Case 15 | Mr. Battle. | Fracture of the forearm. | Anterior and posterior splints. | Pressure sore. |
| Case 16* | Mr. Davies-Colley. | Compound fracture of the tibia and fibula; calf muscles injured. | — | Prolonged suppuration. |
| Case 17* | Mr. Edmund Owen. | Fracture of the upper part of the forearm. | — | — |

* No details of these cases are given in the present paper.

the normal electrical reactions of both muscles and nerves to be the most diagnostic feature of this deformity. It was present in all my cases, and in one case in Table II. the *reactions were taken by Dr. Turney and also by* myself. There is no mention of the electrical reactions in the different books on medical electricity except by Dr. Hedley who says: "It is stated that the electrical reactions are not altered." On the other hand, when one refers to the recorded cases composing Table II. the exact opposite is found in four of those that were examined; out of the 11 recorded these showed reaction of degeneration, in the fifth case the reaction was normal. Dr. Harris, who examined Mr. Page's case, says: "Any ischæmic condition would, I imagine, damage the nerve end-plates as well as the muscles, and one might expect, I should think, some reaction of degeneration." He also mentions the fact that in acute myositis there are no electrical changes until in the late stages, when atrophy, if any, sets in. Dr. Hedley, who examined the muscles of the forearm in Case 12, reported that he obtained reaction of degeneration. Professor Erb states that in a primary muscular condition the electrical reactions are normal. It is possible, however, that he had not examined cases of ischæmic myositis. There are several points against the presence of the reaction of degeneration. 1. One cannot be certain that the nerves were unaffected in those cases in which reaction of degeneration was obtained. 2. If reaction of degeneration was present then we conclude that those muscles are practically paralysed for the time being, and whether this is due to the main nerve trunks being affected or to the motor end-plates makes no difference from a diagnostic point of view. Now, how is it that when the paralysed muscles had their tendons lengthened they could perform the movements of normal *muscles, as they did in Mr. Page's case, and also seem to* have done in Mr. Barnard's case? This is surely peculiar for paralysed muscles to act normally because their tendons are lengthened. It may be that the muscle recovered from the reaction of degeneration, but no absolute statement to that effect is made, and if the nerve end-plates are damaged by the changes in the muscles, as Dr. Harris suggests, it seems quite unlikely that much improvement will ever take place when one considers the fibrous tissue which has taken the place of the muscle fibres. The peripheral nerves are no doubt affected in some of the cases, as in two cases in Table II. the nerves—i.e., ulnar and median—where cut down on and examined were found to be surrounded by fibrous tissue which was adherent to the nerve sheath, and in one case the nerves were rather swollen. In Case 14, although it is not stated, it seems to me that the ulnar and median nerves were seriously injured. A point of particular importance is that the muscular branch of the nerve may be injured in some cases and may cause the reaction of degeneration, while, of course, it is quite possible that these might recover and, in fact, are far more likely to do so than the motor end-plates, which to my mind, for reasons already stated, if they are once injured, must be so for ever. Lastly, what do we know at the present day of the motor end-plates, more especially their relation to electrical reaction?

*Pathology.*—I will simply state here the opinion of the

Wells, and Civil Surgeons Sterne, Bowen, Pickering, Wilkinson, and Buckley have been discharged from hospital to duty.

### The Medical Journal of the Italian Navy.

The *Annali di Medicina Navale* enters upon its eighth year of existence with a double number comprising the parts for January and February, 1902, and consisting of 260 pages, rather more than half of which are devoted to reviews. In a prefatory note the editors apologise for the delay which has arisen from unforeseen causes and is by no means attributable to a lack of material. As a matter of fact they receive a continuous influx of important papers from their colleagues, some of whom are fortunate enough to be following university courses in Italy or elsewhere, while others are charged with the care of the sick in the various naval hospitals, with the sanitary superintendence of these and other establishments, with the supervision of the emigration department, and, in fine, with general medical and sanitary duty in different quarters of the world. Having such a wealth of matter there can be no difficulty in conducting the *Annali* in a satisfactory manner, but it is also the intention of the editors to keep their readers well abreast of all scientific progress wherever it may occur. In the present issue the leading article is by Dr. O. M. Belli who discusses the important question of "Bilge-water in Men-of-War" at considerable length and with much erudition. A shorter paper by Dr. Enrico Bindi on Operative Procedure in Cardiac Traumatic Lesions is also of considerable interest, being admirably illustrated.

### Sudden Deaths in the Russian Army.

During the quinquennium ending December, 1898, there were 537 cases of sudden death among the soldiers occupying the Warsaw district, 204 of the fatalities being ascribed to disease, 223 to accident, and 110 to suicide. Dr. Scherkin, who is the author of a statistical paper on the subject in the *Voienno Medicinski Journal* for October, 1901, does not mention the exact strength of the troops concerned but merely enumerates the various units as follows: infantry, 57 regiments; Chasseurs, seven corps; garrison infantry, 16 regiments; garrison artillery, six battalions; field artillery, 11 brigades; siege artillery, seven batteries; cavalry, 25 regiments; Cossacks, six regiments; sappers, four battalions; pontoon-trains, two battalions; and railway corps, one battalion—in all 142 units, probably comprising about 125,000 men. Deaths from disease were classified as sudden when less than 24 hours had elapsed after admission to hospital.

### Memorial to the late Surgeon-General W. Nash.

The following subscriptions to the above fund have been received since our last notification:—Lieutenant-Colonel E. A. H. Roe, £1 1*s.*; Colonel F. W. Moore, 10*s.*; and Sir J. Fayrer, K.C.S.I., £2 2*s*, making a total of £23 2*s*.

"Audi alteram partem."

## SERUM REACTION IN MALIGNANT ENDOCARDITIS.

*To the Editors of* The Lancet.

Sirs,—In The Lancet of March 22nd, p. 817, is a report by Dr. W. Hale White and Mr. W. C. C. Pakes on a case of malignant endocarditis giving the serum reaction (so-called "Widal" reaction). Upon this I should like to offer a few remarks. I know that it is not quite fair to either author or critic to base arguments on an abstract report. Not having heard the paper read I must excuse myself that it is all I have to go upon. The points at issue are of some importance regarding the value of the test. The authors base the title of their paper on the fact that the serum in this case gave a reaction when diluted 1 in 20 with four strains of the typhoid bacillus and with a fifth partially at 1 in 200. Now I would submit that a reaction occurring in a dilution of 1 in 20 will not suffice for the diagnosis of enterica. The dilution is not high enough. This was pointed out some years ago by myself and others. It is, of course, not often that a blood is found which does react in this dilution, but they do occur occasionally, even in normal individuals. In the case of the fifth sample of typhoid bacillus the fact that it reacted partially in a dilution of 1 in 200 to my mind throws some doubt on the identity of the bacillus or its virulence must have been minimal.

I do not gather from the abstract what the time-limit was or whether the reaction was obtained only after the treatment with anti-streptococcus serum had commenced. Since many bloods will agglutinate if given sufficient time and since horse-serum also often spontaneously agglutinates typhoid bacilli in comparatively high dilution I think these are points of importance, especially the latter, since the reaction seems to have appeared only after treatment had been begun. Should any number of cases occur which give a positive reaction with suitable technique in cases *not* enterica the test will be practically valueless. I have not myself in the course of some experience (based on a dilution of a 1 in 33 and 30 minutes' time-limit) seen any *positive* results in cases where enterica, either past or present, or conferred immunity could be definitely excluded. *Negative* results in cases which are clinically thought to be enterica are comparatively common, especially in the early days of the disease; but in view of recent work by various investigators, as well as of some observations which have come under my own notice, I feel certain that the clinical diagnosis in some of these negative cases has not always been correct. I am, Sirs, yours faithfully,

*Liverpool, March 24th, 1902.* Albert S. Grünbaum.

## DRUNKENNESS AND THE ABUSE OF NARCOTICS.

*To the Editors of* The Lancet.

Sirs,—

> "Intemperance, like a roaring flood,
> Is sweeping o'er our land;
> Its dire effects in tears and blood
> Are traced on every hand."

Everybody deplores drunkenness. Everybody admits that something should be done to mitigate the evil. Everybody will not agree about how the mitigation is to be accomplished. Total abstainers desire their way; prohibitionists and local-vetoists desire theirs. Others think that it would be sufficient to restrict the number and hours of public-houses and to abolish all grocers' licences. The latest proposal hereabout is to make the publicans in populous places—in specified areas of Glasgow and Dundee—close at 10 P.M., the same as in country districts. The most pernicious drinking is in the morning, and it would be much better not to allow any alcoholic beverages to be sold before noon.

It is often said that a nation cannot be made sober by legislation: this nation will never be made sober by any other means. The laws of a nation that would be happy and prosperous should be like the unwritten laws of a well-ordered household, giving every facility to all its members to do well but no facilities to do otherwise. When a member of a family betrays a weakness for alcoholic beverages the use of these beverages in that house is either entirely abolished or very much restricted, and if the same restrictions could be kept up when that weak member was outside the house he would never become, as too often happens, a drunkard and a disgrace to the family. The other members of the family may feel these restrictions somewhat irksome; but they cheerfully acquiesce in the new arrangements for the sake of their weaker member. In the greater family—the nation—it is well enough known there are many weak members, and if restrictions be put upon the procuring of alcoholic beverages which may be somewhat irksome to many, they should not complain for the sake of the weaker members. The total abolition of drunkenness might be quickly accomplished by the Government undertaking the making, importing, storing, and distributing of all alcoholic beverage and, instead of granting licences to publicans to sell these to Tom, Dick, and Harry in indefinite quantities, granting descriptive licences to whoever desires to use these luxuries, with coupons attached for each day's allowance to be given up when obtained. A small sum to be paid for the licence which may be valid for a week, month, or year, and the drink to be paid for when obtained. The day's allowance for an adult should not be more than five fluid ounces of proof spirit, or the alcoholic equivalent of that in any other beverage; and the licence coupons could be so arranged that the day's allowance could be obtained at two, three, or four

*Midwifery*.—D. Cotes-Preedy, Cambridge and St. George's Hospital; G. M. Crockett, Royal Free Hospital; E. F. Forjett, Edinburgh; H. S French, Oxford and Guy's Hospital; H. M Jones, Royal Free Hospital; J. A Kilpatrick, King's College Hospital; M. E. Martin, Royal Free Hospital; H. H. Sloane, St. Bartholomew's Hospital, G. B S. Soper, Guy's Hospital; and S. Zweibach, Königsberg.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: W. T. Colver, S. J. H M. Eastwick Field, H. S. French, E. O. Libbey, S. C. Wilkinson, and J. H. Williams.

THE Dawlish and Teignmouth District Councils have decided to erect a joint isolation hospital.

LARYNGOLOGICAL SOCIETY OF LONDON.—The ordinary meeting of this society has been postponed to Friday, April 11th, at 5 P.M.

VACCINATION GRANT.—Mr. David T. Key, M.R C.S Eng., L S.A., public vaccinator for Wyke Regis, has received for the first time the Government grant for successful vaccination.

AT a public meeting at Peterborough last week it was decided to commemorate the Coronation of King Edward VII. by raising by voluntary subscription a sufficient sum to add a new wing to the hospital presented to the city by the late Earl Fitzwilliam.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—The Organising Committee of King Edward's Hospital Fund for London, 81, Cheapside, E.C., has signified that it has much pleasure in accepting an offer which has been made to it with regard to Mr. Percy Godfrey's "Coronation March." This proposal is to the effect that *6d.* derived from the sale of each copy of the march shall be devoted to the "coronation gift" and that all sums derived from licences to perform the march and collections made at concerts shall be given to the same object. Mr. Godfrey's composition gained the prize recently offered by the Worshipful Company of Musicians for the best coronation march, the adjudicators being Sir Frederick Bridge, Sir Walter Parratt, and Sir Hubert Parry.

THE ROYAL INSTITUTION.—In a lecture on Some Electrical Developments delivered at the Royal Institution on March 22nd Lord Rayleigh said that although the Roentgen rays were so easily produced and were capable of giving such remarkable effects, their essential nature was in several respects unknown. They travelled in straight lines and could neither be refracted nor reflected, from which it necessarily followed that they could not be polarised. Diffraction experiments made with great care by Dutch investigators had led to no result beyond proving that if the rays had an undulatory character their wave length could not exceed the one-hundredth of that of light. As was well known, they produced photographic effects by the decomposition of silver salts and rendered certain fluorescent substances luminous; the only other respect in which they were found to resemble ordinary light was that both the Roentgen rays and the ultra-violet rays of the luminous spectrum caused electric leakage of gases. At one time it was supposed that the Roentgen rays admitted of partial reflection but it was now considered that the apparent effect was probably due to some secondary emission. There were many points of resemblance between Becquerel rays and Roentgen rays. Becquerel formerly believed that the rays discovered by him could be polarised but this view was now abandoned Roentgen rays could be deflected by magnets and experiments were shown in which the rays passing through a hole in an aluminium plate and falling on a fluorescent screen were by means of magnets displaced both in straight lines and in curved lines. Changes produced in jets of steam and water by electrification were also shown In another experiment common air was blown through a Woulfe's bottle containing sulphuric acid which did not cover the end of the inlet tube, so that the air did not bubble through the acid but merely passed over its surface. A jet of steam cast only a faint shadow on a screen when a beam of electric light was turned on it, but when the air from the Woulfe's bottle was directed against the jet of steam the shadow became much darker. When nitric acid was substituted for the sulphuric acid the effect did not take place. Lord Rayleigh said that the cause of this phenomenon was quite unknown and he recommended it to the notice of young experimenters because of the simplicity of the apparatus required.

NOTIFICATION OF CHICKEN POX.—The Bath Rural District Council on March 12th decided to include chicken-pox in the list of notifiable diseases.

BRIDGWATER INFIRMARY.—On March 20th Colonel W. Barratt, the president of the Bridgwater Infirmary, formally opened the new operation room which has been provided by means of a bequest of £300 left for that purpose by the late Mr. George England.

ROYAL HOSPITAL FOR INCURABLES, DUBLIN.—A meeting of the board of governors of this hospital was held on March 18th, when six new patients were elected. The hospital is entirely unsectarian and provides accommodation for 212 patients, including separate wards for the treatment of 72 patients suffering from cancer and consumption, in addition to 140 inmates afflicted with various other incurable maladies, all of whom are disqualified for admission into the general hospitals The average daily number of beds occupied throughout last year was 203 and further financial assistance is urgently needed to reduce a debt of £974.

BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.—During the past year 3285 new out-patients have attended at this hospital, showing a decrease of 38 as compared with last year's figures. The total number of new and old cases treated during the year was 17,174, being 570 less than last year. 440 patients were admitted to the in-patient department, an increase of 13 on last year and the total number of operations was 422, an increase of 12. The number of operations involving abdominal section was 213—that is, nine more than last year; of these nine patients have died, giving a death rate of 4 2 per cent This compares with 2·94 per cent. on 204 operations in 1900.

DOWN DISTRICT LUNATIC ASYLUM.—On March 15th at a meeting of the committee of management of the Down District Lunatic Asylum the following motion with reference to the necessity for the establishment of a central laboratory in Ireland for the investigation of the pathology of insanity was unanimously carried: "That we, the committee of management of Down District Asylum, desire to express our warm approval of the proposed central laboratory for research in the pathology of insanity; we hereby state our readiness to affiliate this institution with such an undertaking when it assumes a practical shape and to contribute towards its maintenance a sum of £25 per annum We are of opinion that the project is deserving of general support, believing, as we do, that the prevention and the most effective treatment of mental disease must be largely aided by an accurate knowledge of the morbid physical conditions associated with it, and feeling that any step that tends to promote such knowledge must ultimately prove an important factor in the reduction of the burden of the lunacy charges of the country."

DONATIONS AND BEQUESTS TO HOSPITALS.—The Lord Mayor and Lady Mayoress of London have contributed 20 guineas to the Royal Hospital for Diseases of the Chest, City-road, London, towards the fund now being raised to build and to furnish a home for the nursing staff.—The committee of the Hospital for Consumption, Brompton, has received £1000 from the Goldsmiths' Company and £105 from the Mercers' Company for the country branch of the hospital at Bagshot where the open-air treatment of phthisis is to be carried out.—By the will of Miss Frances Hester Robinson of Richmond £2000 are bequeathed to the British Home for Incurables at Streatham, £2000 to the Deaf and Dumb Asylum in the Old Kent-road, £2000 to the School for the Indigent Blind (for the Junior Branch at Wandsworth), £2000 to the Society for Granting Annuities to the Poor Adult Blind, £1000 to the Charing-cross Hospital, and £1000 to the Hospital for Consumption and Diseases of the Chest, Fulham-road.—Under the will of the late Miss Olivia Atherton of Everton the Royal Infirmary (Liverpool), Northern Hospital (Liverpool), Southern Hospital (Liverpool), and Liverpool Country Hospital for Chronic Diseases receive £1000 each; the Hospital for Women (Liverpool), the Eye and Ear Infirmary (Liverpool), the Liverpool Dispensaries, Liverpool Children's Infirmary, Bootle Hospital, and Stanley Hospital receive £500 each; the Children's Convalescent Home at West Kirby, Wirral Children's Hospital, Home for Incurables, Cancer Hospital (Liverpool), and Liverpool Hospital for Consumption receive £250 each; and the Wallasey Cottage Hospital (Liverpool) receives £200 times. Special licences could be granted as now for special occasions and to responsible persons who would guarantee that there would be no abuse of the beverages; and as all the alcoholic drinking of the country would be under the eye of the Government any abuse of these licences or privileges could soon be put down.

About 30 years ago a circular was sent to all the medical men in this district "asking them to refrain as much as possible from prescribing alcohol in any form." My reply was that I prescribed castor oil when required and *that I expected when the patients got* better they would cease taking it, and that I expected that if I prescribed any alcohol the patients would do the same. I received another notice that many drunkards alleged that the beginning of their bad habits took place when they were under medical treatment, which may be quite true in some cases. Certainly it is perfectly true that many women begin to use alcohol in some form for painful menstruation and during puerperal weakness, and many others have begun to use narcotics by a medical man being either too busy or too lazy to write a prescription, telling his patients to go into the nearest druggist's and purchase a narcotic and take so much of it. Much drunkenness and narcotic-consuming might be prevented by medical men always and only administering alcohol and narcotics medicated in a prescription, not to be repeated unless sanctioned by the prescriber.

Thanking you in anticipation of your finding room in your valuable journal for the above, and hoping that other members of our profession may be induced to state their opinions how best to combat these evils,

I am, Sirs, yours faithfully,

Paisley, March 18th, 1902. J. B. HUNTER.

## A NATIVE REMEDY FOR BLACKWATER FEVER.

*To the Editors of* THE LANCET.

SIRS,—I have read with great interest the notes by Dr. D. R. O'Sullivan-Beare in THE LANCET of Feb. 1st, p. 282, on the native remedy for blackwater fever and I should like to offer a few suggestions on this most important subject.

Before dealing with the question of the remedy there are several points raised in this paper as to the nature of blackwater fever which call for some comment. In the five cases quoted the patients had either never tasted quinine or at least had not taken it for two months previously, so that this adds one more to the many facts which militate against the dangerous doctrine that quinine is the cause of blackwater fever which has prejudiced large numbers against the use of quinine. I most emphatically differ from Dr. O'Sullivan-Beare in his view that blackwater fever is not a form of malarial fever, and I consider that "the test of practical experiment" is in favour of the use of quinine in its treatment. I believe it to be an assumption which has not been proved that the hæmoglobinuria is caused by a toxin rather than by the parasite itself, and the idea which is suggested that nephritis is set up in *ordinary* cases is in my opinion an erroneous one, the albumin present being due to the presence of hæmoglobin. The mention of two cases of blackwater fever occurring among negroes is interesting, as I do not think this is common, and it will be still more important if the information can be borne out which Dr. O'Sullivan-Beare has obtained concerning *some tribes in* the interior, "amongst whom blackwater fever would appear to be endemic"; but may not this be hæmaturia due to bilharzia hæmatobia?

Having delivered myself of these criticisms I desire to thank your correspondent most heartily for the interesting particulars which he has given us concerning this native remedy, for although I do not agree with his estimate of the value of quinine in this disease there can be no question that we are in need of other remedies, and I think that after the testimony we have received *Cassia Beareana* should receive a full trial. As to its mode of action and the reason for its usefulness a few remarks may not be out of place. The most important points in the treatment of blackwater fever, apart from any specific malarial treatment, are to maintain the flow of the urine and to deal with the vomiting which is often a dangerous feature of the malady, making it difficult to administer either food or medicine and weakening the patient. It seems to be a point in the prescription of this medicine to give it with a great deal of fluid, and probably this assists in promoting free diuresis, even if the drug itself is not a diuretic. But what interests me more is the influence which it appears to have upon vomiting. In the cases mentioned vomiting seems to have been a prominent symptom and the medicine seems to have relieved it. Perhaps even more striking than the effect of the remedy upon blackwater fever is the result obtained in so-called bilious remittent fever. I have sometimes wondered whether the number of cases classed under this head are all of them malarial; at all events the trouble here is usually vomiting and this the medicine seems to relieve. If this is so, the drug may be useful in other cases where vomiting is a troublesome symptom and it is to be hoped that all who use it will note carefully the effects produced, so that we may not be acting in the dark in prescribing the remedy.

I am, Sirs, yours faithfully,

CHARLES F. HARFORD-BATTERSBY.

Livingstone College, Leyton, E., March 24th, 1902.

## VAGARIES OF VACCINIA.

*To the Editors of* THE LANCET.

SIRS,—From personal experience of the vagaries of vaccinia I am intensely interested in the clinical note sent you by Dr. J. W. Washbourn, published in THE LANCET of March 8th, p. 664. It is within the recollection of many of your readers that when the Local Government Board first introduced the glycerinated calf-lymph it was found to be very irregular and uncertain in action. A not uncommon experience was to make four careful scarifications, insert the glycerinated calf-lymph from the same tube in each, and then to find quite a variety of vesicles, papules, blebs, and minute vascular spots, these last resembling small nævi, none of them coming to maturity and disappearing without leaving a cicatrix; one class of immature vesicles left a slight scar more like staining of the skin than a scar.

I have notes of a case almost identical with the one recorded by Dr. Washbourn. In March, 1899, I vaccinated a child, a female, aged two years, in four places. Two of the scarifications developed into mature vesicles leaving well-marked cicatrices; the other two were simple blebs, with no areola; the serous fluid was re-absorbed, the vesicles shrank and never scabbed. The mark left was more like a stain than a cicatrix. After a lapse of nine months the mother complained that whenever the child had a cold the vaccination spots came back. At first I treated this piece of curious information as purely mythical—on a par with many of the funny things said about vaccination. However, to please the mother I asked her to let me see the child's arm when she had the "spots" on again. This she did in the course of a few weeks, when, to my surprise, at the site of the *imperfect vesicles only* the superficial layer of the epithelium was raised in the form of two or three small vesicles resembling exactly a group of herpes; be it noted there were none in the cicatrices left by the mature vesicles. I saw them two days after the child scratched them; they were red at the base and covered by a scab. To prevent further scratching the arm was dressed; the sores soon healed and left *no scars*. Now, it may be due to over-dulness, but it requires a stretch of the imagination to fancy that in this case the vaccinal virus in the original lymph was of two kinds—one active, producing satisfactory results; the other inert, lying dormant for nine months and then by the aid of a cold or, as in Dr. Washbourn's case, scarlatinal infection developing its latent powers in producing good results. Or shall we put it this way—the more or less inert lymph having exhausted its strength in its first abortive effort, by a further period of rest in the living tissue acquired sufficient vitality when reinforced by scarlet fever to produce true vesicles.

With your permission, Sirs, I should like to ask so great an authority as Dr. Washbourn one or two questions. His patient was vaccinated in four places, "only *one* of which took and that very slightly," yet we are informed further on that Mr. Percy Rose found four spots on the left arm at the usual site of vaccination. Query, were there cicatrices "at the usual sites of vaccination"? Again, and more important, did the four spots, "exactly like mild vaccination at about the seventh day," leave cicatrices behind them like genuine cases of primary vaccination? Is it not generally the case that the concurrence of scarlet fever, whooping-cough, and

Health of Tiverton Rural Distict.—Mr. J. R. R Pollock, the medical officer of health, reports that during 1901 the birth-rate in this Devonshire rural district was 25·51 per 1000, and the death-rate was 14·81 per 1000.

Defective Drains.—At the Bristol County Court on March 18th a tenant claimed from the owner of a house £50 damages for alleged breach of warranty respecting the drains. The plaintiff stated that when he took the house from the defendant he was assured that the drains were in perfect condition. After a few months members of the family were constantly ill and one child died from diphtheria. Eventually the plaintiff communicated with the sanitary authority and the drains were found to be defective. The defendant stated that he gave no warranty; all he said was that to the best of his belief the drains were all right. Judgment was given for the plaintiff for £25, with costs.

Cheltenham General Hospital.—The annual meeting of the subscribers to this institution was held on March 18th under the presidency of Colonel Croker-King. The medical report stated that 896 in-patients had been admitted during 1901, against 871 in 1900, and there had been 8867 out-patients treated compared with 7936 in the preceding year. The financial statement showed that there was a small increase in church collections and Hospital Saturday collections and the legacies received amounted to £2250, but the excess of expenditure over income nevertheless amounted to £2419. Colonel Croker-King was re-elected president.

Torbay Hospital, Torquay.—There is some difficulty at Torbay Hospital with respect to a rule which was adopted by the committee last year providing for the annual election of the honorary medical staff. At the recent election two of the physicians, who were originally appointed for life, were not re-elected although they were thanked for their past services. The board of management then advertised for two gentlemen to fill the vacancies. The members of the profession in Torquay at a meeting agreed that none of their number should apply for the appointments and consequently no applications were received. The honorary medical staff of the hospital feel strongly on the subject of the rule alluded to and six influential governors have requisitioned a special meeting with the object of getting the rule altered.

Winsley Sanatorium.—A public meeting in aid of the proposed sanatorium for consumptives for Somerset, Wilts, Gloucestershire, and Bristol was held at Bath on March 13th under the presidency of the Mayor (Mr E. E. Phillips, L R C P. Edin., M R C.S Eng.). Dr. L. Weatherly mentioned that the members of His Majesty's Advisory Board who recently visited the Winsley Sanatorium, although they regarded it as an admirable spot for such an institution, found that the space would be too small for the erection of the King's Sanatorium for which Sir E Cassell had given £200.000. It was stated that £20,000 would be needed for the erection of the proposed sanatorium; £5000 had only been received at present, and it has been resolved that the foundation-stone shall not be laid until one half of the required sum has been raised.

Birmingham General Hospital.—The report of this institution for 1901 states that the old hospital which was sold to the corporation has now been pulled down and a building which for 130 years did so much for the relief of the sick and suffering passes away in all but memory. The demand on the beds, though great in previous years, has been even greater during the past year, the list of cases awaiting admission often exceeding 200 and it has rarely dropped to 100. The number of in-patients was 5170, a decrease of 41 as compared with the previous year. The daily average of patients in the hospital was 278, against 281½ in 1900. Of the in-patients admitted 902 were children under 12 years of age, of whom 138 were under the age of two years. The out-patients numbered 62,643, or 1778 more than in the previous year. The amount accruing from subscriptions, &c., was £7747 17*s.* 8*d.*, or £469 3*s.* 8*d.* more than in the previous year. Donations amounted to £582 0*s.* 5*d* and special congregational collections to £52 0*s.* 5*d.* £2973 6*s* 8*d.* were placed to the credit of the current account as the moiety of legacies received during the year. The ordinary expenditure was £24,411 9*s.* 11*d.* and the extraordinary expenses amounted to £812 17*s.* 2*d.*, while the sum of £276 8*s.* 5*d.* was transferred to the Jaffray branch account to meet the deficit at that institution. An adverse balance of £5110 19*s.* 1*d.* remained at the end of the year, the surplus of £1180 5*s.* 10*d.* shown on the year's working being applied to the reduction of the deficit of £6291 4*s.* 11*d.* brought over from last year.

Health of Launceston.—Dr. C. G. Gibson, the medical officer of health of Launceston (Cornwall), in his annual report for 1901 states that during the year the births numbered 59 and the deaths 48. The birth-rate was 14·5 per 1000 and the death-rate was 11·84 per 1000. Dr. Gibson urged the town council to provide an isolation hospital for small-pox cases.

Dorset County Hospital, Dorchester.—The sixty-first annual report of this institution which has just been issued states that 299 in-patients were admitted during 1901, against 311 in 1900. The out-patients numbered 961 compared with 996 in the previous year. The average daily number of in-patients was 33; the average cost per patient weekly amounted to £1 0*s.* 2*d.* The financial statement shows that the receipts for the year amounted to £2165 and the expenditure to £2284. The deficit balance at the end of 1900 amounted to £18 and this has now been increased to £137. During the present year it is hoped to provide the hospital with a new operation room, and owing to munificent donations from the Earl of Eldon and the Earl of Ilchester the committee hope that the work will be completed without any call being made on the general funds of the institution.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

### *Midwives Bill.*

In anticipation of the report stage of the Midwives Bill several amendments have been prepared and put down on the notice paper of the House of Commons. Mr. Griffith Boscawen and Mr. Robert Ambrose propose to raise once more the question of the scope of the legislation by moving amendments to make it apply to all women who habitually and for gain attend midwifery cases, while Mr. George Harwood has put down a notice to strike out the subsection inserted at the instance of Sir John Batty Tuke in the Grand Committee which proposes that no woman shall be entitled to recover fees in the courts unless she is certified under the Act. In Clause 2 Mr. T. P. O'Connor will move to strike out the words which give special recognition to the certificates in midwifery of the Royal College of Physicians of Ireland and the Obstetrical Society of London. Several amendments appear in the notice paper with reference to Clause 3, the clause dealing with the constitution and duties of the Central Midwives Board. Mr. Patrick White proposes that the General Medical Council and not the Lord President of the Privy Council shall take the steps for the formation of the Board; Mr. McGovern that the four registered medical practitioners shall be appointed by the General Medical Council instead of by the Royal College of Physicians of London, the Royal College of Surgeons of England, the Society of Apothecaries, and the Incorporated Midwives Institute; and Mr. Griffith-Boscawen that the Royal British Nurses Association shall have a nominee on the Board. With this substantial body of amendments on the notice paper the Bill cannot be taken as unopposed business after midnight. In all probability, therefore, it will have to wait its turn with other private Members' Bills for consideration on a Wednesday after Whitsuntide, unless, of course, the Government arranges to give special facilities.

## HOUSE OF COMMONS

*Tuesday, March 18th.*

### *Vaccination in Government Departments.*

Mr. Channing asked the Vice-President of the Committee of Counc on Education whether he was aware that on Feb. 19th a general orde was issued on behalf of the Board of Education and signed by S William Abney inviting the officers of the department at Sout Kensington to submit themselves for vaccination and revaccinatio by the public vaccinator on Feb. 25th and 26th, and desirin those who did not wish to do so to send in their names t the heads of their sections; whether there had been issue since then a further minute, signed by Sir William Abney, invitin officers who still remained unwilling to reconsider the matter befo the Board proceeded to decide what further steps should be taken whether any similar action had been taken on the elementary side a Whitehall and in other Government departments; whether the orde and minute were issued by Sir William Abney with the sanction c the Lord President and Sir George Kekewich; and, if so, under wha powers, statutory or by regulation, any further steps to compel th officers to be vaccinated or revaccinated could be taken.—Mr. Gran Lawson, replying for Sir John Gorst, said: Notices relating to th vaccination of persons in the employ of the Board of Education hav by the authority of the Board been issued both at Whitehall and Sout Kensington. Similar notices have, I am informed, been issued b other Government departments. No person can be compelled by th Board of Education to be vaccinated or revaccinated.

measles modifies rather than accentuates the vaccinal process? My own interpretation of the phenomenon was that it was either herpes or due to some other irritant producing dilatation of the capillaries of the cutis causing the superficial layers of the epithelium to be raised from the deeper in the form of a bleb.

I am, Sirs, yours faithfully,
March 24th, 1902. J. MACKENZIE.

## BEEF-WORM IN THE ORBITAL CAVITY.

*To the Editors of* THE LANCET.

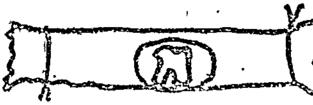
SIRS,—In connexion with my article "Beef-worm in the Orbital Cavity," published in THE LANCET of Jan 4th, 1902, p. 19, I have received the following suggestions from Mr. Ernest Austen who has charge of the collections of diptera in the British Museum. The so-called beef-worm, he thinks, is the larva of a species of dermatobia, probably *Dermatobia cyaniventris*, a dipterous fly belonging to the family œstridæ I stated that the egg had been laid by the parent fly *beneath* the human skin or mucous membrane, but Mr. Austen suggests—and no doubt rightly—that the egg was laid *upon* the skin and that the larva, on hatching, burrowed beneath the surface in the subcutaneous tissue, which would account quite satisfactorily for the extraordinary position in which it was found. I stated that in the full-grown worm the bristles encircling the middle two-thirds of the body attained a length of half an inch. This statement had never been verified by personal experience, as the longest bristles I have seen on the creature have never exceeded one-twelfth of an inch, but I considered my authority reliable. Mr. Austen, however, informs me that the bristles *never* reach a length of half an inch in *any* dipterous larva.

I am, Sirs, yours faithfully,
Corozal, British Honduras, March 4th, 1902. THOMAS GANN.

## INTESTINAL OBSTRUCTION CAUSED BY A TOOTH.

*To the Editors of* THE LANCET.

SIRS,—On Sunday, Feb. 9th, I was called to see a dentist in this neighbourhood and on arrival found him dead. He was taken suddenly ill the night before with colic but I was not sent for till too late. I performed a necropsy and found all the organs normal. However, about midway between the duodenum and large intestine I found an obstruction in the shape of a hard foreign body. I removed the piece of intestine and on examination found a molar tooth encysted in a membrane which had become attached to the inner wall of the gut thus.



It was a natural tooth and had evidently been there for a long period.

I am, Sirs, yours faithfully,
GODFREY WARNES.
Great College street, N.W., March 23rd, 1902.

## CANCER IN INDIA AND IN CHINA.

*To the Editors of* THE LANCET.

SIRS,—In THE LANCET of to-day (March 22nd) Lieutenant-Colonel Maitland, I.M.S., writes that, "To say, as Mr Keetley does, that I [i.e, Lieutenant-Colonel Maitland] alone am responsible for all the medical and surgical wants of 30,000,000 Hindoos in Southern India is as absurd as it would be to say that Mr. Keetley was responsible for the whole population of London." This seems to be Lieutenant-Colonel Maitland's idea of a fair description of the following sentence in my letter in THE LANCET of Jan. 18th (p 193) · "Captain Donovan says that Colonel Maitland speaks for the Madras General Hospital where cases from all over the Madras Presidency come for operation." I see nothing absurd in this statement of Captain Donovan.

Every London surgeon who once gets "known" does draw his cases from among the 5,000,000 of Londoners and from far beyond; but his position differs from Lieutenant-Colonel Maitland's in this: that there are 50 other surgeons as well known as himself practising in the same city with the Londoner, while the professor of surgery's position is unique at Madras. Therefore, the fact that the latter "almost always has one or two" Hindoo patients suffering from cancer is no proof of their suffering from it as much as Europeans.

I am greatly obliged to Lieutenant-Colonel George Ranking, I.M.S., for his valuable letter.

I am, Sirs, yours faithfully,
Grosvenor-street, W., March 22nd, 1902. C. B. KEETLEY.

## LOCAL OPTION IN VACCINATION.

*To the Editors of* THE LANCET.

SIRS,—I see that the town council of Hastings on March 21st passed a resolution to request Parliament in this session to abolish the conscientious objector clause and also to make revaccination compulsory. Seeing the difficulty of legislation now would it not be well to allow towns or counties who prefer it, say by a two-thirds majority, to adopt such regulations at once? Surely a short Act to that effect might be got through Parliament. The result of a few years' experience would then be convincing.

I am, Sirs, yours faithfully,
GEORGE HENDERSON, M.D., F.L.S.
Bushey, March 22nd, 1902

## DIPHTHERIA OF THE CONJUNCTIVA.

*To the Editors of* THE LANCET.

SIRS,—One or two small errors have crept into the report published in THE LANCET of March 22nd, p. 818, of a paper on Diphtheria of the Conjunctiva read before the Ophthalmological Society on March 14th. The report represents me as insisting upon the practical value of an immediate examination of "smears" of the discharge, "stained in methyl-eosine, and the acid reaction *of gelatin cultures*." What I actually did was to insist upon the value attaching to the staining of cover-glass preparations by Neisser's plan and to the acid reaction of bouillon cultures.

I am, Sirs, yours faithfully,
Welbeck-street, W., March 23rd, 1902. SYDNEY STEPHENSON.

## THE DIPLOMA OF THE SPECTACLE-MAKERS' COMPANY.

*To the Editors of* THE LANCET.

SIRS,—Sir W. Hart Dyke's letter in THE LANCET of March 15th, p. 774, does not meet the case. He says the Company "do not examine in sight-testing." This is evading the question, as the greater part of the examination deals with visual optics and spectacle-fitting, and the Company's official instructor is a gentleman who teaches visual optics only; his printed circulars and advertisements are issued *by the Company* with the particulars and syllabus of the examination, and in one of these circulars he undertakes for a substantial fee to coach for the examination, partly by correspondence and partly by personal tuition at a class held in London during the two weeks immediately preceding the examination. In fact, the worshipful Company provides the examination for a substantial fee and thoughtfully circulates the advertisements of its official instructor who will for another substantial fee endeavour to cram sufficient information into the competitor to enable him to pass, and further thoughtfully provides that if the candidate cannot pass it all at once he may do so by instalments at successive examinations.

I am not raising the question as to whether opticians should or should not test sight but I do say that the intention of the original optical committee is not being carried out, that the present methods are calculated to do serious harm, because, though the examination is no proof of anything beyond the fact that the diploma holder possesses a certain amount of optical knowledge, the diplomas are being used for the purpose of inducing the public to believe that they have been granted for proficiency in knowledge particularly connected with the fitting and adapting of spectacles to correct defective eyesight and are used for advertising purposes to draw trade in the shape of the sale of spectacles. This is shown by the fact that some of the holders attach the letters F.S.M.C. to their names in their

### *The Water-supply at Darenth.*

Dr. FARQUHARSON asked the President of the Local Government Board (1) whether he was aware that the Kent Waterworks Company had nearly completed a large pumping station in the parish of Darenth in the Darenth valley, within 1100 yards of the inclosure at Gore Farm in which the Metropolitan Asylums Board had also nearly completed small-pox hospitals to hold a total of 2500 cases; and that the pumping station was at a lower level than any part of this inclosure; and (2) seeing that these small-pox hospitals and the other establishments belonging to the Metropolitan Asylums Board at Gore Farm had no means of drainage for liquids other than soakage into the porous gravels and sands overlying the chalk strata from which the Kent Waterworks derive their supply, whether he would institute an inquiry into the effect on the quality of the water supply from this drainage, including that from the burial-ground belonging to the Metropolitan Asylums Board at Gore Farm, in which between 1500 and 1600 interments of small-pox and scarlet fever patients had been made, this burial-ground being situated 160 feet higher than, and 1700 yards distant from, the Kent Waterworks Company's pumping station.—Mr. GRANT LAWSON replied for Mr. LONG, saying: I am aware of the facts mentioned in the first paragraph of the question. The well was approved by me in December last as a source of supply after an investigation by an inspector and after samples of the water had been examined by experts and found to be of great organic purity. I am informed that there is no danger of the well being polluted by surface drainage as it is lined with closely fitting iron cylinders to a depth of 92 feet from the surface, the lower 60 feet being in the solid chalk. Moreover, I understand that Gore Farm drains into a subsidiary valley of the Darenth, which enters the main valley fully half a mile below the site of the well, and it is therefore impossible for surface drainage from the hospital lands to reach the vicinity of the well.—Dr. FARQUHARSON asked whether the Local Government Board would send down an inspector in order to relieve the local anxiety on this subject.—Mr. GRANT LAWSON: An inspector was there as recently as last November. He made a close inspection and, as I have said, the water was then submitted to analysis, I do not think it is necessary to do it again.

## THURSDAY, MARCH 20TH.

### *Vaccination Questions.*

Mr. ROUND asked the President of the Local Government Board if his attention had been called to the danger of infection in schools from children who had not been vaccinated; and if he would take steps, if necessary by legislation, to empower school authorities to exclude such children from attendance at school.—Mr. LONG replied: I am aware of the danger referred to where small-pox is prevalent but it mainly affects children who are not protected by vaccination. I may, however, point out that under Article 88 of the Code of Regulations made by the Board of Education, the managers of any public elementary school must comply with a notice of the sanitary authority of the district or of two members acting on the advice of the medical officer of health, requiring them for a specified time with a view to preventing the spread of disease to exclude any scholars from attendance. There is a right of appeal to the Board of Education if the notice is considered unreasonable. I understand that in one case unvaccinated children have been excluded under the article.

Mr. CORRIE GRANT asked the President of the Local Government Board whether he was aware that Dr. S. M. Copeman inoculated monkeys with small-pox material obtained from cases under observation during outbreaks of the disease, that he inoculated calves from the vesicles so produced on the monkeys, and inoculated a considerable number of children from the vesicles so produced on the calves, as described by himself in a paper read before the Royal Medical and Chirurgical Society on Dec. 10th, 1901; whether these experiments were conducted with the knowledge of the parents or with the knowledge or sanction or at the expense of his department; and whether Dr. Copeman was now or had been in the employment of the Government.—Mr. LONG, in reply, said: The answer to the first two points is in the affirmative. I am informed that a considerable number of children were vaccinated with the lymph obtained from the calves referred to but none of the vaccinations were performed by Dr. Copeman. I have no information as to whether the experiments were conducted with the knowledge of the parents of the children vaccinated but they were not performed with the knowledge or sanction or at the expense of the Local Government Board. Dr. Copeman is one of the medical inspectors of the department.

## FRIDAY, MARCH 21ST.

### *Enteric Fever among the Troops in South Africa.*

Sir WALTER FOSTER asked the Secretary of State for War if he could state the names of the special sanitary officers who had been sent to South Africa to inquire into the origin and spread of enteric fever and other preventable diseases among the troops, with the dates of their appointments, the length of time spent in South Africa on these duties, and the duties on which they were now engaged.—Mr BRODRICK replied: Three gentlemen were specially employed in August, 1900, to inquire into the subjects mentioned—Dr. Simpson, Colonel J. L. Notter, R.A.M.C., and Major Bruce. Dr. Simpson served until November, 1901, with an interval of five months, when he was employed on plague duties. He has now gone to Hong-Kong to investigate the recurrence of plague there. Colonel Notter served till October, 1901, when he returned to England. He is now acting as principal medical officer at Aldershot. Major Bruce served till October, 1901. He is now serving on the Advisory Board for Medical Services. Captain Beveridge and Colonel Cooper, R.A.M.C., who were already in South Africa, were also employed in the same work. The recommendations of these gentlemen are being carefully carried out by the responsible medical officers on the spot.

While the House was in Committee of Supply discussing the vote for the salaries and expenses of the War Office Sir WALTER FOSTER made a speech on this subject. He argued that the wastage among the troops from enteric fever was not taken sufficiently seriously. During the months of January and February of the present year there had been 800 deaths among the soldiers—a mortality heavy in itself and representing a large amount of disability through sickness. This drain on the forces, he submitted, was not creditable to the administration. He had been told by the Secretary of State that he was advised by civilian medical men in the best practice in London, but what he stood in need of were the guidance and advice of special experts in sanitary matters—leading medical officers of health or experienced inspectors under the Local Government Board. There were no fewer than 60 places where the mortality from enteric fever was excessive. The disease was preventable and he thought special pains should be taken to protect the soldiers from it. He would like to know whether anything was being done in the way of providing the columns with the means of boiling water.—Mr. BRODRICK said that he agreed with the hon. Member as to the seriousness of the wastage from this disease, but he would remind him of the difficulty there was in enforcing any regulations or precautions that might be prescribed. Regulations might be enforced in a civil community, but the case was entirely different with a moving army scattered over so wide a region as South Africa. Soldiers tired and thirsty would drink water whenever they came across it. A column arrived at a place and while food was being prepared the men in defiance of regulations made off to the river and drank the water. In this way the very best precautions were rendered of no avail. At the same time he fully appreciated the force of the hon. Member's speech and he assured him that the matter would have his best efforts and attention.

### *Medical Staff of the Refugee Camps.*

Mr. LAMBERT asked the Secretary of State for the Colonies whether any of the medical staff of the refugee camps had complained of their treatment by the chief superintendent, and whether the same had been dismissed by him without notice or reason assigned.—Mr. CHAMBERLAIN said: No, sir; I have not received any complaints, but I think that I ought to add that I have absolute confidence in Sir William Maxwell, the superintendent of the concentration camps and the military governor of the district, and that I should not think of interfering with his discretion in dealing with his subordinates.

## TUESDAY, MARCH 25TH.

### *Colonel's Pay in the Royal Army Medical Corps.*

Captain NORTON asked the Secretary of State for War if he could state the total pay and allowances of a colonel on the general staff, a colonel on the staff of the Royal Engineers, and a colonel of the Royal Army Medical Corps respectively, and whether any increase of total emoluments for the last-mentioned officer had been arranged for in the forthcoming warrant for the Royal Army Medical Corps.—Lord STANLEY replied for Mr. BRODRICK: The pay and allowances are as follows: Colonel on the staff, £880 and forage; Colonel on the staff (R.E.), £1063 and forage; Colonel of the R.A.M.C., £880 and forage. The recent Committee on the Reorganisation of the Army Medical Service did not recommend any increase to the emoluments of colonels of the Royal Army Medical Corps and no increase is therefore provided for officers of this rank in the forthcoming warrant.

### *Small-pox Statistics.*

Mr. CORRIE GRANT asked the President of the Local Government Board, having regard to the fact that the system of classification of small-pox deaths, according to a footnote in the weekly return of the Registrar-General, excluded from the classes of vaccinated and not vaccinated all cases not so certified by registered medical men and that cases were put under the heading "no statement" not only when the medical practitioner was unable to certify whether there had been vaccination or not but when the practitioner had failed to make any mention of vaccination, whether he would direct the Registrar-General to secure a stricter classification of the small-pox deaths.—Mr. GRANT LAWSON, for Mr. LONG, replied: I have communicated with the Registrar-General who states that he does at present secure a classification of small-pox deaths which is sufficiently accurate for statistical purposes. Frequently it is not practicable to obtain full information concerning particular cases in time for publication in the current weekly returns but from time to time the information is supplemented with the help of facts subsequently obtained. The Registrar-General will, however, consider whether any alteration shall be made as regards the publication of vaccination statistics in connexion with deaths from small-pox.

### *Bubonic Plague in Hong-Kong.*

Mr. WEIR asked the Secretary of State for the Colonies if he would state the percentage of the bubonic plague cases in Hong-Kong for each month since August last inclusive; and, in view of the fact that the plague was largely attributed by the Legislative Council of Hong-Kong to the prevalence of rats, would he say whether effect had been given to the council's proposals to employ an English rat-catcher; and, if so, with what result.—Mr. CHAMBERLAIN replied: The number of plague cases in Hong Kong was—for August, 20; for September, 22; for October 3; and one case occurred in each of the three months, December, January, and February. I have urged upon the Colonial Government the necessity of destroying rats and very large numbers have been killed, but no such proposal as that referred to by the hon. Member has been brought to my notice.

### *Typhoid Fever Epidemic in Ireland.*

Mr. TULLY asked the Chief Secretary to the Lord Lieutenant of Ireland if he could say what was the nature of the report of Dr. McWeeney as to the outbreak of typhoid fever in Boyle Union in connexion with a local creamery; and could he state why no steps were taken to act on this report and to close the creamery during the epidemic. —Mr. WYNDHAM said in reply: The report was unfavourable. The creamery was closed for some days, during which the structural defects were remedied. The Local Government Board inspector considers the creamery may now be worked without danger to the public health.

business advertisements, presumably to imply a professional qualification and also advertise themselves as "qualified by examination." Many of these men have scarcely any practical knowledge of the trade at all and do not even profess to understand anything but spectacles.

I may mention that I and eight of my assistants have passed this examination but refrain from making any public use of the fact.

I am, Sirs, yours faithfully,
JAMES AITCHISON,
Citizen and Spectaclemaker; Member of the Original Optical Committee of the Worshipful Company of Spectaclemakers.
Strand, W.C., March 18th, 1902.

## SIR JAMES PAGET'S LECTURES.

*To the Editors of* THE LANCET.

SIRS,—Old students of Sir James Paget and the many who enjoy and profit by his few preserved lectures may be glad to be directed to your first volume for 1869. There they will find three lectures which have never been republished as well as that on the Treatment of Carbuncle which is included in the volume edited by Mr. Howard Marsh. The other lectures were on "Diseased Joints of the Foot," Jan. 30th; "Treatment of Fracture," Feb. 27th; and "Aneurysm of the Femoral Artery," April 7th and 24th. The last is of special interest. As the headings show, they were all reported for THE LANCET at the request of the Editor, being revised by Sir James Paget. To THE LANCET belongs the credit of their preservation. This is a greater service than it might seem because they are perhaps the only hospital lectures of Sir James Paget preserved as delivered. He went through the reports but hardly altered a sentence. The lectures were given without a note and present perfectly his extempore style.

I am, Sirs, yours faithfully,
March 25th, 1902. THE REPORTER OF THE LECTURES.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*Plague Riot in Patiala.—Further Increase of the Epidemic.—Samaritan Funds for Indian Hospitals.—Cholera Inoculations.—Researches in Malaria.*

ON Feb. 19th a somewhat serious disturbance took place in Patiala which is said to have been occasioned by the compulsory segregation of two cases of plague. Major H. Hendley, I.M.S., medical adviser to the State, and Dr. Nathu Mau, the civil surgeon, were attacked by a large mob with sticks and bricks and in consequence of being wounded had to take refuge in the branch dispensary. This was then wrecked and set fire to but the troops arrived in time and the officers were able to effect their escape. The plague camp near the railway-station was also set on fire. According to another account Major Hendley was fastened down by a door, was pelted, and was then carried off and thrust into a mass of filth. He was wounded in nine places—most seriously on the head and on the right leg. These disturbances are not common now but their recurrence serves to show that the dangers to which plague workers are subject are very real.

The plague mortality for the whole of India has again increased. During the past week there have been 14,946 deaths, as against 12,695 for the previous seven days. There were 5922 deaths in the Punjab (an increase of 1809), 4373 in the Bombay Presidency (an increase of 543), 1351 in the North-West Provinces, and 863 in Bengal (an increase of 125). In Bombay city and in Calcutta the disease is growing apace. Bombay had a plague mortality of 701, the general mortality being 1635, equal to a rate of over 105 per mille. Calcutta had 176 plague deaths, an increase of 56, and later figures show a very rapid development. Karachi records 47 deaths, the Madras Presidency 543, Mysore State 507, and Kashmir 317. The old idea that plague is favoured by cold weather is not quite extinct but the continued development with a rising temperature in such places as Bombay and Calcutta ought to correct this fallacy. During the corresponding week of last year there were only 6307 deaths, so that the present serious increase of the disease should be noted.

There are not many hospitals in India which have Samaritan funds, so that the recent gift of Rs. 10,000 by Messrs. Ralli Brothers to the Medical College and Mayo Hospitals in Calcutta is particularly happy. It is intended to be used for clothing and the distribution of small sums for temporary assistance to poor native convalescents—Hindoos, Mahomedans, and Parsees.

Some interesting observations have been made by Major Buchanan and Captain Lamb on the effects of cholera inoculations which may be thus summarised: (1) a preliminary injection of a dead vaccine a few days before the living material is inoculated has the effect of increasing the subsequent constitutional disturbance (the larger the dose of the former the greater the subsequent reaction); (2) a slight increase in the amount of living material greatly increases the constitutional disturbance; and (3) a previous attack of cholera (within one month) decidedly lessens the reaction of a "living" inoculation. The chief inoculations for cholera are now at Goalundo, where the coolies for the tea-gardens pass through, but the returns for cholera are optional on the employers so that the information available is scanty.

Other interesting observations which are shortly to be published refer to researches on malaria fevers by the commissioners. The amount of infection of children is a trustworthy index of the general prevalence of malaria and the "endemic index" is determined by the proportion of children and of anopheles found to be infected. What is true for Africa seems to be true also for India. The endemic index was found to range very widely, from *nil* in Calcutta to 72 in the Duars. In Calcutta not one of the children examined had parasites and not one of the anopheletes dissected was infected. The commissioners, however, recognise malarial disease accompanied by parasites and a form without it. The latter is common in Calcutta, is grave in type, and passes into a true malarial cachexia with a large increase in the mononuclear leucocytes. The actual number of anopheletes present in a district is no criterion of the prevalence of malaria. In the Duars anopheletes are comparatively difficult to capture. All species of anopheletes are evidently not equally dangerous and it is thought that anopheles Rosii, a very prevalent species, is hostile or immune to the parasite. Other observations made are that while in the cold weather zygotes would not develop beyond a certain stage they progressed to sporozoites when the infected mosquitoes were warmed by means of an incubator.

Feb. 28th.

## MAIDSTONE AFTER THE EPIDEMIC.

(BY OUR SPECIAL SANITARY COMMISSIONER.)

*(Concluded from p. 701.)*

*The Diphtheria Epidemic.—The Good Effect of Sewer Ventilating Shafts.—The Sewage Disposal and Drainage Schemes.—Other Measures.—Dangerous Street Hydrants.*

WHEN insisting on the necessity of looking to the sewers and domestic drainage of Maidstone, instead of considering only the water-supply, it was pointed out that typhoid fever was not the only disease that seriously menaced the health of the town. Indeed, except for the great typhoid fever epidemic of 1897, diphtheria was doing more damage. During the six years previous to this epidemic there had been 498 cases of diphtheria notified and only 116 cases of typhoid fever. Then when, in 1897, typhoid fever assumed an epidemic form diphtheria did the same, but the typhoid fever epidemic exhausted itself in a few weeks while the diphtheria epidemic lasted three years. There were 211 cases notified in 1897; this increased to 240 in 1898, to 213 in 1899, and ceased only in 1900, when, however, there were still 50 cases. During these three years there were only 35, 23, and 28 cases of typhoid fever respectively. If we take the 10 years from 1891 to 1900 there were in all 2082 cases of typhoid fever notified, and this includes the great epidemic. But though there has been no such great epidemic of diphtheria it will be found that during these same 10 years no less than 1212 cases of that disease were notified. Consequently, if something is not done to check the prevalence of diphtheria it is possible that in the course of years the cases of diphtheria will exceed in number even those of typhoid fever. This danger is so serious that the Local Government Board held an inquiry on the subject in 1899. It was then shown that the schools had served as a

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

Adams, Harold Cotterell, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Paignton and Marldon Districts by the Totnes Board of Guardians, vice Dr. J. Hamilton Ward.

Allan, Hector, M.B., C M. Aberd., has been appointed Medical Officer of Health to the Whalley Bridge Urban District Council.

Barnes, Arthur Stanley, M.D., M.R.C.P Lond., B.Sc., has been appointed Senior House Physician to the National Hospital for the Paralysed and Epileptic, vice Dr. Singer, resigned.

Beattie, R., M.D. R.U.I., has been re-appointed Medical Officer of Health to the Soothill Upper Urban District Councils.

Behrendt, M. R J., L.R.C.P., L.R.C.S. Edin., has been re appointed Medical Officer of Health to the Scunthorpe and to the Brumby and Frodingham Urban District Councils.

Breton, Lancelot M., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer and Public Vaccinator to No. 3 District of the South Stonham Union.

Bullmore, Charles Cecil, L.R.C.P., L.R.C.S, Edin., L F.P S. Glasg , has been appointed Medical Officer for the Falmouth and Truro Port Sanitary Authority, vice Dr. W. King Bullmore, resigned.

Buzzard, E. Farquhar, M.A., M.B., M.R.C.P. Lond., has been appointed Assistant Physician to the Belgrave Hospital for Children.

Forbes, R., M.D. Glasg., has been re-appointed Medical Officer of Health to the Eastwood Urban District Council.

Forsyth, R., M.D Glasg., has been re-appointed Medical Officer of Health to the Drighlington Urban District Council.

Hamilton, John, M.D. Durh., F.R.C.S. Edin., has been re-appointed Medical Officer of Health to the Swadlincote Urban District Council.

Jones, Helena G., M.B. Lond., has been appointed Assistant Medical Officer to the District Asylum, Mullingar.

Parsons, Francis John Crane, L.R.C.P. Lond., M.R.C.S., L.S.A., J.P., has been re-appointed Medical Officer of Health for the Bridgwater Urban District.

Phillips, G. G., M.R.C.S., L.S.A., has been appointed Medical Officer of Health to the Tickhill Urban District Council.

Phillips, Hubert C., M.R.C.S. Eng., M. & L.S.A. Lond., has been appointed Anæsthetist to the Female Lock Hospital, Harrow-road, W.

Soltau, Grace, L.R.C.P. & S. Edin., has been appointed House Surgeon to the Belgrave Hospital for Children.

Stewart, Thomas Grainger, M.B., Ch.B. Edin., has been appointed Junior House Physician to the National Hospital for the Paralysed and Epileptic, vice Dr. Barnes.

Turner, Dawson, B.A., M.D. Edin., has been appointed Examiner in Experimental Physics to Edinburgh University.

Vernon Ethel M., M.D., B.S. Lond., L.S.A., has been appointed Pathologist to the New Hospital for Women, Euston-road.

Wolfe, James Francis, M.B., C.M. Edin., has been appointed Medical Officer to the Heavitree (Exeter) Isolation Hospital.

Worger, Richard George, L.R.C.P. Lond., M.R.C.S., L.S.A., has been re-appointed Medical Officer and Public Vaccinator for the Kilmersdon District by the Frome (Somerset) Board of Guardians.

## Vacancies.

*For further information regarding each vacancy reference should made to the advertisement (see Index).*

Bedford County Hospital.—House Physician. Salary £60 pe annum, with board, lodging, and washing. Also Senior Hou Surgeon. Salary £100 a year, with apartments, board, an washing.

Birmingham Workhouse Infirmary.—Assistant Resident Medic Officer. Salary £100 per annum, with apartments, rations, &c.

Brentford Union Infirmary and Workhouse.—Assistant Medic Superintendent, unmarried. The person appointed will be requir to devote his whole time to the service of the guardians. Salar £120 per annum, with apartments, rations, washing, &c.

Bridgwater Infirmary.—House Surgeon. Salary £80 a year, wit board and residence.

Central London Ophthalmic Hospital, Gray's Inn-road, W.C. Refraction Assistant. Salary at rate of £50 per annum.

Chelsea Hospital for Women, Fulham-road, S.W.—Pathologist.

City of London Union Infirmary.—Assistant Medical Superi tendent, single, or widower without children. Salary £150 p annum, with apartments, rations, and washing.

Durham County Hospital.—House Surgeon, also Assistant Hou Surgeon. Salary of Senior £100, Junior £65, with board and lodgi in each case.

Essex and Colchester General Hospital.—House Surgeon. Sala £100 a year, with board, washing, and residence.

Guy's Hospital.—Demonstrator of Bacteriology and Bacteriologis Salary about £180, rising to £200 per annum.

Hospital for Consumption and Diseases of the Chest, Brompto —Resident House Physicians for six months. Honorarium £25.

Leeds General Infirmary.—Honorary Dental Surgeon.

Leicester Infirmary.—Assistant House Surgeon. Salary £80 p annum, with board, apartments, and washing.

Lincoln Hospital for the Insane, The Lawn.—Assistant Medic Officer. Salary £100 a year.

Liverpool Royal Southern Hospital.—Junior House Surgeo Salary 60 guineas per annum.

Norfolk and Norwich Hospital.—House Surgeon, unmarrie Salary £80 per annum, with board, lodging, and washing.

North-Eastern Hospital for Children, Hackney-road, N.E.—Hou Physician for six months. Salary at rate of £60 per annum, wi board, residence, and laundry.

Northumberland House, Finsbury-park, N.—Assistant Medic Officer. Salary £120 per annum, with board, &c.

Nottingham General Dispensary.—Assistant Resident Surgeon, u married. Salary £160 per annum, increasing by £10 every yea with apartments, attendance, light, and fuel.

Oldham Infirmary.—Senior House Surgeon. Salary £100 per annu with board, residence, and washing.

Paddington Infirmary.—Clinical Assistant and Second Assista to the Medical Superintendent, unmarried, for six months. Hon rarium £36, with board, lodging, and washing.

Parish of St. Pancras, London.—Senior Assistant Medical Offic (Resident). Salary £135 per annum, with allowances.

Royal South Hants and Southampton Hospital.—Assista Physician.

Royal University of Ireland.—Examiners in Surgery, salary £5 Midwifery, salary £35; Pathology, salary £25; and Ophth mology, salary £20; in each case with travelling allowances.

St. Pancras and Northern Dispensary, 126, Euston-road.—Honora Surgeon.

Sheffield University College.—Demonstrator in Bacteriologic Laboratory. Salary £150, rising to £200 per annum.

South Lambeth, Stockwell, and North Brixton Dispensar Albert-square, Clapham-road.—Vacancy in Visiting Medical Staff.

Tottenham Hospital.—House Surgeon. Salary £50 per annum, wit board, residence, and laundry.

Tunbridge Wells General Hospital.—House Surgeon, unmarrie Salary £100 per annum, with board, apartments, gas, firing, an attendance.

Victoria Hospital, Folkestone.—House Surgeon. Salary £100 p annum, with board, residence, and laundry.

## Births, Marriages, and Deaths.

### BIRTHS.

Chambers.—On March 19th, at The Priory, Roehampton, the wife James Chambers, M.D. R.U.I., of a son.

Evans.—On March 23rd, at Upper Wimpole-street, the wife Willmott Evans, M.D., F.R C.S , of a son.

Fawssett.—On March 16th, at Stratford road, Sparkbrook, Birmin ham, Ethel, wife of Basil Fawssett, M.R.C.S., L.R.C.P. Lond., of son.

Hunnard.—On March 18th, at Mansfield, Notts, the wife of Arth Hunnard, M.B., B.S. Lond., prematurely, of a daughter.

Pearson.—On March 18th, at Aliceedale, South Africa, the wife Maurice Grey Pearson, M.B. Lond., of a son.

### DEATHS.

Caddy.—John Turner Caddy, M.D., died on March 21st at Charte house, Lion Gate-gardens, Richmond, Surrey, aged 80.

Phillips.—On March 19th, at Porchester-square, Francis Addis Phillips, M.R.C S., L.R.C.P. Lond., aged 30.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

focus for the spread of the disease and that when the schools were closed by order and disinfected or adjourned for the holidays the prevalence of the disease abated.

Apart from the closing and disinfecting of schools Dr. Charles Pye Oliver, the present medical officer of health, attributes the gratifying reduction in the number of cases of diphtheria notified during the year 1900 to the construction of a number of ventilating shafts in connexion with the main sewers and to the more general and more efficient flushing of the house drains. As a consequence there has been, he states, a marked decrease in the number of complaints received concerning the offensive odours that used to issue from the street manholes. As already mentioned, four ventilating shafts were constructed in 1897. There were three more erected in 1898 and two in 1899. This was altogether insufficient, but there had been so much talk about the contamination of the water as the cause of disease that the authorities did not yet fully realise the absolute necessity of ample ventilation for the sewers. The fact, previously mentioned, that in the two years following upon the typhoid fever epidemic improvements in domestic drainage had been effected in 7776 cases, while this had been done in only 2794 cases during the previous two years, shows that the importance of this phase of sanitation had been appreciated. It was also understood that more sewers and better sewers had to be built, for the length of new pipes laid amounted to 37,714 feet during the two years following upon the epidemic; this contrasts favourably with the 9250 feet laid in the two previous years. But it does not seem to have been fully realised that though the construction and condition of both private drains and public sewers may be improved, still sewer air will force itself upon the population if the sewers are not efficiently ventilated. This danger is greatest at the high levels, and sewers going down a steep incline are apt to become ventilating shafts for the sewers which they join at a lower level. So long as the air can travel upwards it will do so in a straight line and without seeking side issues. But when stopped suddenly at the top end of the sewer the air will then expand and seek an issue at the nearest point. The pressure may be so great that the sewer air can then force its way even through a well-constructed syphon-trap and thus enter the houses that are on the higher levels. This may explain why by far the greater number—indeed, nearly all—the cases of typhoid fever occurred among those who lived 100 feet or more above the main collectors. Now, at last, this fact has been appreciated and during the year 1900 16 new ventilating shafts have been introduced at the termination or summit of the sewers, and thereupon the epidemic of diphtheria ceased. The figures for the year 1901 have not yet been published, but I am told that seven or eight more ventilating shafts were erected last year. Diphtheria still maintained its hold on the town and there were 82 cases notified in 1901; but this gives an annual average of 66·5 cases for the two years following upon the erection of numerous street sewer ventilators as opposed to an annual average of 221 3 cases during the three years preceding this improvement in sewer ventilation Of course, this incident taken by itself does not suffice to prove that inefficient sewer ventilation was the one cause of the widespread prevalence of diphtheria and of typhoid fever, but doubtless it contributed to render the population more susceptible. There is good reason to believe that diphtheria especially was spread by personal contact at the schools, where, for instance, some children drank by putting their mouths to the same tap instead of using glasses Nevertheless, it is obvious that means must be taken to prevent people breathing the air that comes from sewers, especially when, as is the case at Maidstone, these sewers are not all self-cleansing.

The question now arises as to what still remains to be done so that Maidstone shall no longer be exposed to the risk of yet another great epidemic. The two most difficult, because they are the most expensive, reforms needed relate to the disposal of its sewage and the reconstruction of its main collecting sewers so that they shall be self-cleansing. The wisest and the cheapest course would be to unite the two questions and to make the one scheme serve both purposes. Unfortunately, the condition of the sewers at present holds quite a secondary position. The inquiries made and the reports published deal mainly with the disposal of the sewage rather than with the sewers themselves. The first report was made by the borough surveyor, Mr Bunting, and by Mr. W. J. Dibdin and was presented to the town council in October, 1900 This report estimates the flow of sewage at 30 gallons per head, or 1,020,000 gallons per day, and states that the sewage is sometimes of an exceptionally bad quality in consequence of the admixture of refuse from manufactories. In the course of July, 1897, two bacteria beds, a coarse and a fine bed, were constructed for experimental purposes. They had been working satisfactorily for two years. The solid matter held in solution was completely removed. What was oxidisable in the sewage was extracted to the extent of 69 per cent., and the nitrogenous matter, as measured by albuminoid ammonia, to the extent of 75 per cent. The effluents steadily improved in quality when kept either in open or closed bottles; this, it is claimed, proves conclusively that under no circumstances could they injuriously affect the condition of any stream into which they might be discharged. The land actually disposable for the treatment of sewage amounts to nine and a half acres. According to the Local Government Board regulation, for a population such as that of Maidstone there should be at least 20 acres and the greater portion of the nine and a half acres available is unsuitable for the purpose. Therefore a new site must be secured. The first likely site is near at hand, but it could not be reached without pumping the sewage up to a height of 80 feet. The second site proposed would involve the extension of the outfall to a distance of 633 yards, and then what is qualified as very suitable land would be reached below Allington lock. In this case pumping is also necessary, but only to a height of 25 feet. There is, however, a serious objection. The water company has its pumping-station on the north side of the river Medway immediately opposite this area and has sunk a well near its engines. Then there is residential property in the neighbourhood and it is anticipated that the owners would raise objections. Finally, this land is occasionally flooded. A third outfall is suggested at Millhall and New Hythe, where the land would be cheaper, but it would be necessary to obtain a leave of way from the present outfall at Allington Lock and to pump up the sewage 25 feet. The beds might be cheaper, as they could be sunk in the ground and thus would save the cost of sustaining walls It will be seen that all these schemes are subject to serious objections, and under these circumstances it was only natural to seek further advice. Therefore Mr James Mansergh was selected to give an expert report on the question and this second report was published in September, 1901. It also presents a confusing variety of schemes, and there is no agreement as to the principle to be adopted. Shall the sewage be purified by land irrigation? shall such irrigation be preceded by bacterial treatment? or will the bacterial treatment alone suffice? Naturally the last proposal would be preferred if the Local Government Board gave its consent. In that case a much smaller site would suffice. The beds, four feet deep, would cover 7·494 acres, with an extra 1·264 acres for storm water, making a total of 8 758 acres. Then, according to the Local Government Board requirements, there ought to be 17 acres more for irrigation with the effluent. If, however, the bacterial treatment was absolutely perfect there would be no need for the 17 acres. Mr. James Mansergh argues that the proximity of tidal waters and the character of the sewage renders Maidstone a typical place for the application of the bacterial method. Otherwise the only really suitable site is at New Hythe or Lansford, and this is the farthest from the town and the most expensive. Here the outfall into the Medway would be considerably below and beyond the Forstal Well and the waterworks.

Without, however, attempting to give any definite opinion as to the respective merits of these different sites I am more concerned in urging the necessity of diverting the greater part of the sewage from the main collectors that follow the course of the river and are not self-cleansing. The schemes mentioned involve the necessity of pumping the sewage up to reach the site selected. Obviously, it would be preferable to construct a main intercepting collector at a higher level which would bring the sewage by gravitation to the site secured. The sewage of the small portion of the town situated below this high-level collector might continue to flow into the existing main collectors; but perhaps the amount of this sewage would be so reduced that pipe sewers placed inside the main collector would suffice to carry it away, and their cleanliness might be more easily maintained The larger sewer could be used for rain-water only. In other words, the separate system might be adopted for the lower levels, and the amount of the sewage that would have to be pumped up would thus be greatly

## SCOTTISH POOR LAW MEDICAL OFFICERS

If our readers will turn to THE LANCET of March 8th 1902 page 685 they will find an annotation under the above heading giving particulars of the differences between Dr G Nicoll, the medical officer of the parish of Clyne Sutherland and some of the ratepayers Since then another meeting of ratepayers has been held at Brora on Feb 28th in consequence of the Parish Council of Clyne not having acted upon the resolution of the ratepayers' meeting held on Feb 11th demanding the dismissal of Dr Nicoll Mr Andrew Ross a ratepayer and a member of the county council was elected chairman The reply from the clerk of the parish council addressed to this gentleman and dated Feb 13th was read It acknowledged the resolution passed on Feb 11th and stated that he had written to the chairman of the parish council (Mr Sharp) for instructions The chairman of the meeting said that he had heard nothing from that gentleman and thus they had met again Four motions were then put to the meeting and carried nem con The first resolution was to the effect that the ratepayers meeting was dissatisfied with the parish council in its still retaining the services of Dr Nicoll and dissatisfied with the chairman Mr Spark for his lack of immediate action The second resolution appointed a deputation of 12 ratepayers to wait upon the chairman of the council to learn his proposed action and requesting him to call an early special meeting of the council The third resolution determined that should the parish council not take immediate action the matter be brought before the Local Government Board and the Medical Board The fourth embodied the finding of the meeting that the officer should be dismissed instantly with payment of three months salary in advance. Several councillors spoke at the meeting and it appeared that six months ago a motion was brought forward in the council to dismiss Dr Nicoll, that five voted for it and five against and that the chairman gave his casting vote in favour of keeping him It is hardly necessary to add that the most prominent speakers at the ratepayers meeting were some of the five who voted against the motion in council This seems to have been the *primum mobile* of the matter The chairman stated that the result of the deputation would be communicated to the ratepayers at a subsequent meeting A deputation was then appointed which met the chairman of the parish council on March 3rd He is reported to have replied that as the letter accompanying the resolutions was addressed to the council as a body he declined to take any action

An interesting correspondance has been running in the pages of the *Northern Times* on this subject One of the malcontents states that the parochial board of 12 years ago took steps to have a medical officer for its own parish and paid him £47 beyond the regular salary for attending paupers so that it could have a medical man nearer and at a cheaper rate to attend the other parishioners 'Lex Terræ' in reply says he does not believe that the statement is correct, he states that such an arrangement is illegal and refers to the thirty first annual report (1876) of the Board of Supervision whose decision in a similar case was that it was illegal to expend the funds raised for the relief of the poor in order to provide cheaper or more convenient medical attendance for persons who are not paupers He refers also to the second annual report of the Local Government Board (1896) where it is pointed out that the inhabitants of a parish might make such arrangements as they saw fit to induce a medical man to settle in the parish but these conditions could not enter into the contract between the parish council and its medical officer

It seems to us that after being so narrowly defeated at the council meeting the minority have raised an agitation amongst the ratepayers starting with the assumption that their medical man is a sort of club doctor to the parish whom they have forced to accept a composition of a part of his proper fees and in consequence that he is like the parochial fireman always at the beck and call *nolens volens* of any parishioner especially an obtrusive ratepayer

## GREEK FOUNDLING CHILDREN IN CONSTANTINOPLE

THE LANCET of April 6th 1901 p 1020 we reviewed a work by Dr Spiridion C Zavitziano of Constantinople in which that gentleman gave a very favourable account of the methods adopted by the Greek community in Pera for the rescue of foundlings a system which has been in operation for about 12 years Two or three months ago the Œcumenical Patriarch appointed a commission to consider whether the same system of caring for foundlings could be extended to the other suburbs of the Turkish capital, and this commission recommended the establishment of a maternity hospital with a view to the discouragement of abortion and infanticide A serious difficulty has however, now arisen because since the report of the commission has been printed the Turkish Government has issued an order to the police by which all the foundlings of Constantinople whether they are of the Christian religion or not must be sent to the poor asylum where, up to this date, the results have not been at all encouraging For instance out of 112 children admitted there only eight are now alive whereas among the foundlings of Pera taken care of by the Greek community the death rate is only 4 per cent or less Among about 80 of these last mentioned children only two died during the month of January and none during the month of February. Under these circumstances it seems to be hardly possible to justify the new regulation made by the Turkish Government

## FLUORIDES IN MEDICINE

*To the Editors of* THE LANCET

SIRS —I shall be very much obliged if any of your readers can give me any information in connexion with the medicinal or other use of hydrofluoric acid and its compounds and as to any injurious effects which may have resulted from their administration I find that there is an increasing tendency to use them as food preservatives I have noted references with regard to their use in Martindale and Westcott s Extra Pharmacopœia ninth edition

I am, Sirs yours faithfully,
A L P

March 18th 1902

## MR RAWKINS REDIVIVUS

At the Plymouth County Court on March 12th Mr William O T. Annesley L S A Lond brought an action against Mr H O Lambart L R C P, L R C S Edin for £5 balance of fees for acting as locum tenent in April May, and June, 1900 during which time plaintiff took charge of defendant s surgery at a salary of £2 2s a week Letters were read in court from defendant stating The surgery to pay expenses must make at least £4 per week so charge them more and put in second bottles and plasters ointments and lotions whenever you get the chance I saw you had given a six ounce bottle to a child five years old and the dose marked on it was one teaspoonful three times a day Now you will see we shall never make a fortune at that rate Kindly remedy this Give to a child of that age a one and a half ounce bottle charge 1s and order a teaspoonful every two or three hours so that they may come back next day The defence was that plaintiff did not perform his duties satisfactorily His Honour Judge Lush Wilson K C gave judgment for plaintiff for £2 18s 11*d* and costs

Does anyone we wonder, ever read nowadays a novel by Albert Smith called The Adventures of Mr Ledbury ? If so he will remember the scene when Johnson announced that Mrs Stokes wanted four more draughts and would call for them by and by

> ' Very good replied Mr Rawkins Suppose you make it six. The bread bill will be heavy this week and I shall want some ground bait on Friday The extra three shillings will cover it
>
> Bob shouted Mr Prodgers Where are the clean phials?
>
> "There ain t none answered Bob ' I hadn t time to shot em
>
> We can send a mixture instead said Johnson I can wash out this Reading Sauce bottle in a minute
>
> No no by no means returned Rawkins don t put her up to it The minute people find that a three shilling mixture holds more than four eighteen penny phials they put the skid on the draughts, wait for the little bottles

So does history repeat itself but it is the kind of history which needs no repetition Mr Lambart s situation was made to wear as undignified an appearance as possible but he has his own letters to thank for this It is an unfortunate fact that the medical man can always obtain thanks and sometimes payment for medicine while his undiluted advice is very generally rewarded by neither This attitude of the public which is tantamount to a demand for a constant supply of drugs compels medical men occasionally to order medicine so as to ensure their instructions being followed It may also be here and there responsible for a revival of the policy of Mr Rawkins, but we repudiate utterly any suggestion that such unworthy tactics are often resorted to by members of our great and philanthropic profession

## STERILISED DRESSINGS IN PACKETS

Messrs Maw, Son and Thompson have sent us a specimen packet of sterilised dressings The specimen submitted to us contains Lister s cyanide wool It is carefully packed in three papers the outer being merely a covering layer Within this is a layer of parchment paper carefully sealed with paraffin wax and within this again another layer of thin paper It is stated that the wool and the two inner coverings are carefully sterilised before putting up and it is evident that the strict observance of all precautions will enable the surgeon to carry with him enough dressing for one case or so in a handy form

## RARE MEDICAL LITERATURE

Two rare old quasi medical works were included in the sale of Lord Mexborough s library at Sotheby s auction rooms Wellington street W C recently The first consisted of eight leaves printed in a bold Gothic letter 24 letters to a full page and believed to have been issued by W de Machlinia of London in the year 1483 The title runs Here begynneth a litill boke necessarye and behoveful ayenst the Pestilence" and the introduction states The Bisshop (Ramicus) of Arusiens in the royame of Denmarke doctour of Phisike will write by the moost experte and famous doctours reduced and an economy would be effected. The point is to cut in two the long branch sewers which, going down from the highest latitudes to the river bank, act as ventilating shafts to the big collector built at the water side. The high-level intercepting collector, being built on high ground, could be given a sufficient fall to be self-cleansing. Thus the adoption of a new system for the disposal of the sewage should be made to coincide with the introduction of a better system for the drainage of the whole of the town. This would entail a greater outlay, but it is always cheaper in the long run to do what has to be done once for all and thoroughly.

By the side of vast schemes of this description, which are of no productive value, there is a good opening for smaller enterprises at Maidstone, such as the building of a municipal common lodging-house and artisans' cottages which might be made a source of municipal revenue. Also, there are many complaints as to the collection of household refuse and this likewise might be undertaken by the municipality and done more efficaciously. It should be possible in an agricultural centre like Maidstone to sell some portion of the refuse at a remunerative price. Then there are private courts and alleys where the scavenging is very inefficient. As these are not public thoroughfares it is not the business of the municipality to keep them clean and in such places decaying organic matter is apt to accumulate. The owners should see to its removal, but the fact remains that they neglect to do so; and as in such places gratuities are not forthcoming the refuse collectors are also liable to be forgetful. But if the refuse was collected by municipal servants and was a source of municipal revenue such negligence would be less likely to occur. There is yet another point which is a matter of detail but might lead to serious consequences if neglected. The system for closing the street hydrants cannot be qualified otherwise than as dangerous. In the vertical pipe that rises from the main to reach the surface of the street there is an enlargement forming a little chamber big enough to hold a gallon of water. Here is placed a vulcanite ball which is forced up to close the upper aperture by the pressure from the main below. To open the hydrant a key is introduced which presses this ball out of place and then the water surges up into the street. This is all very well so long as the main is full and the pressure is strong enough to hold up the ball in its place. But the effecting of repairs, or intermittent supply during dry seasons, or other causes may reduce this pressure, and then the ball falls from its position. Dirt and water from the street can then enter the space where the ball is kept and thence can reach the main to mix with the water which the inhabitants drink. There are 279 such hydrants in Maidstone, and it is not to be expected that in all cases they should invariably remain in proper working order. This system was adopted some 40 years ago. It was then considered ingenious, but now it is quite obsolete and a safer apparatus should be employed. The medical officer of health in his last report describes a specimen of water which contained nematodes four inches long. He suggests that in its embryo stage the nematode burrows into certain insect larvæ which are swallowed by water-beetles and other aquatic insects. Here it becomes encysted and is discharged by the beetle into the water, where it develops into young and perfect nematodes. The pathogenic germ might, with equal facility, reach the water-supply through these defective hydrants. Seeing how much work has now been accomplished to improve the general sanitary condition of Maidstone it is not too much to hope that the remaining sanitary defects will soon be swept away. In this manner will the great typhoid fever epidemic have proved itself a blessing in disguise.

## MANCHESTER.

(From our own Correspondent.)

### *Jubilee of Owens College, Manchester.*

The Prince and Princess of Wales visited Manchester on March 12th in connexion with the jubilee of Owens College and the opening of Whitworth Hall, the latest addition to the collegiate buildings. They arrived at the Victoria station at 10.50 A.M., accompanied by their host and hostess, the Earl and Countess of Derby, and were met at the station by the Lord Mayor and other officers of the corporation of Manchester. They then proceeded to the college, where the Duke of Devonshire, the President of the college, and Principal Alfred Hopkinson received their Royal Highnesses. After a reception by the governors and senate in the Christie Library, a procession was formed which included the teaching staff and lecturers. Several distinguished Members of Parliament, notable professors, and eminent ecclesiastics were present, including Earl Spencer, Chancellor of the Victoria University. Thus escorted into the hall the Prince and Princess took their seats on the right of the Duke of Devonshire, the audience rising and singing "God Save the King." The Duke of Devonshire thanked the Prince and Princess for their presence at the celebrations and said that the idea of the founder was to provide in that great centre a university to supply higher education in such branches of learning and science as were usually taught in English universities. It was laid down as a fundamental and immutable rule that the governors, teachers, and students should be subject to no religious tests. The address of welcome from the college authorities was then read by the Principal. Afterwards Alderman Thompson presented to His Royal Highness on behalf of the council a gold key of the hall. The Prince expressed the pleasure of himself and the Princess at being there that day to join in the celebrations and to open the beautiful hall. He regretted the absence of the architect (Mr. Alfred Waterhouse) and of Dr. A. W. Ward and Sir Henry Roscoe through illness. He said also that a college which after five years of its existence was reduced to 33 students and yet could persevere in the path which had been originally marked out, and which could now boast of 32 professors and over 1000 students, had indeed earned a just right to celebrate with pride and satisfaction its first jubilee. He also made sympathetic reference to the names of Owens, Beyer, Christie, Whitworth, and other benefactors of the college, and paid compliments to the great teachers and students who had by their genius and force of intellect maintained in the college a high standard of learning, and added that the presence there that day of the governing body and the representatives of the municipalities of Manchester and the neighbouring towns should serve to strengthen the mutual sympathy and guide the college in its work. He called attention to the special effort recently made to raise a fund to pay the amount of the indebtedness of the college, which was very considerable, and to provide against an annual deficit, and said that the fund had now reached £100,000, which, however, was only enough to carry on the extended work of the college without making additions to the staff and appliances which it was desirable should be made. He was sure that Manchester men would not allow this institution in any way to suffer from want of funds. He then declared the Whitworth Hall open. The meeting was addressed by Sir R. C. Jebb who took the place of Dr. Ward as "representative of literature" and by Professor Rücker as "representative of science." Thanks for their addresses were voted on the motion of Sir F. Adam. The Prince subsequently at the town hall received an address of welcome from the corporation of Manchester and made a suitable reply; he said that had it been practicable to include in that day's proceedings the opening of the new school of technology he would gladly have taken part in that ceremony. The Prince and Princess, with about 300 other guests, were entertained to luncheon in the principal room of the hall. The Prince referred to the recent tour of the Princess and himself and also said that he was sure that they were all happy to see present amongst them so many distinguished representatives of foreign and colonial universities, who had come to take part in the proceedings. On the way to the Victoria station the Royal procession halted at the west porch of the cathedral for the unveiling of a statue of Queen Victoria, the work and gift of Princess Louise, Duchess of Argyll. The Royal departure for Knowsley took place a few minutes after 4 P.M. Several of the tradespeople who occupy premises along the line of the route of the Royal procession offered to give to the hospitals the money received from letting their windows to sight-seers. The Lord Mayor approved the idea and mentioned that as regards subscriptions Manchester compared unfavourably with other large cities. It is to be hoped that the hospitals will benefit considerably by this generous offer.

### *Manchester and Salford Sanitary Association: Jubilee Conference.*

The committee of this association has decided to hold a Conference on Sanitary Reform in commemoration of auctorised in Phisike somme thinges of the infirmyte of pestilence which dayly enfecteth and sone suffreth us to departe oute of this lyfe." This was sold for £160, the purchaser being Mr. Quaritch. The other work referred to was of the date 1652, the author being George Fidge, and the title "The Great Eater of Grayes-Inne, or the Life of Mr. Marriot the Cormorant, Wherein is set forth all the Exploits and Actions by him performed; with many pleasant Stories of his *Travells into* Kent *and* other places. Also a rare Physicall Dispensatory, being the manner how he makes his Cordiall Broaths, Pills, Purgations, Julips, and Vomits to keep his Body in temper and free from Surfeits." This realised £11 5*s*.

## A QUESTION OF FEES.

*To the Editors of* THE LANCET.

SIRS,—When attending a club patient with a *dangerous* aneurysm I at his request called in and conferred with my medical neighbours. Since the decease of the patient I find that the widow expects the club to pay the consultation fees, also my fee for meeting them in consultation. I have always made a rule of charging club patients a fee when I meet any medical man in consultation, and I think I am within my rights in so doing. Will you kindly express your view on the matter

I am, Sirs, yours faithfully,

March 25th, 1902. CONSTANT READER.

⁂ We think that such extra services rendered by the club medical officer as attending at a consultation should be paid by the patient or his representatives and not by the club. The patient or his representatives should also pay the consultation fees of the medical gentlemen called in to consider the case with the club medical officer.—ED. L.

## WANTED—A HOME.

*To the Editors of* THE LANCET.

SIRS,—Can any reader kindly recommend a comfortable home, in London or suburbs, where a lady, aged 76 years, would be well cared for? She is bedridden from right hemiplegia with contractures (no aphasia), and cannot pay more than £2 a week.

I am, Sirs, yours faithfully,

Teignmouth, Devon. F. CECIL H. PIGGOTT, M.D. Cantab.

## A WARNING.

*To the Editors of* THE LANCET.

SIRS,—A canvasser for a trade directory is calling at the houses of medical men at an hour when they are probably out and interviews their wives or housekeepers. He represents that the name of the medical man was in the last edition of his trade directory and asks sometimes 2*s*., sometimes 3*s*., for a re-insertion. His manner is plausible and he generally gets the money.—I am, Sirs, yours faithfully,

Romford-road, Forest Gate, March 21st, 1902. STEPHEN SMITH.

## COUNTRY HOUSE SEWAGE DISPOSAL.

*To the Editors of* THE LANCET.

SIRS,—I should be obliged if any of your readers would tell me the best way of dealing with the sewage of a country house having about one acre of ground. At present the sewage is conveyed into an underground covered tank made of unmortared walls, so that the liquid drains into the surrounding gravelly soil, the surface being thickly planted with trees. In wet weather the overflow comes to the surface and is at times offensive. The present system has been in operation or 12 years without causing any trouble, but now the soil is becoming "sick" and is a nuisance. The house is built on the slope and the soil is stony and porous. I am, Sirs, yours faithfully,

March 22nd, 1902. M.D.

## A CAUTION WITH RESPECT TO SAMPLES.

*To the Editors of* THE LANCET.

SIRS,—A tin box containing Bipalatinoids No. 581, forwarded by Messrs. Oppenheimer, Son, and Co., Limited, was incautiously opened and one of the bipalatinoids fell on the floor. My favourite cat played with it and ate it. In about half an hour after it was reported in a fit and when I saw it it was dead. It had micturated and its limbs were contracted. I referred to the prescription on the box and found inscribed —Ferrous carbonate (pil. Blaud), aloin, strychnia, ac arseniosi, āā gr. $\frac{1}{30}$, pulv. capsici, gr. $\frac{1}{4}$. Dose, one after meals. Strychnia gr. $\frac{1}{30}$ was the amount taken by the cat which caused its death by poisoning. If animals are about one should not be satisfied until such samples are burnt in the fire, as no other disposal is safe. I hope this may be a warning to others. I am, Sirs, yours faithfully,

F. A. PURCELL, M.D. R.U.I.

Manchester-square, W., March 24th, 1902.

## HOW DISEASE IS SPREAD.

TWO persons were fined 40*s*. each at the Glasgow Sheriff Court on March 20th for concealing cases of small-pox which had occurred in their respective houses. In the first case the defendant pleaded that the patient refused to see a medical man because he feared being sent to a hospital. The case was not discovered until after the patient's death. In the second case an Irishman was the accused. The first intimation which the sanitary authorities received was through the police who had been informed by neighbours. When the medical officer called and asked to see the patient who was sa to be suffering from small-pox he was shown an elder sister and w told that she was the only girl in the house. On going into t kitchen, however, he found a young girl lying in bed, hidden l bedclothes, who was suffering from small-pox. The school boa officer had been told that the girl was staying with some friends i Ireland. The elder sister was the only member of the household w had been revaccinated and she was nursing the patient notwit standing the fact that she was employed at home by a firm dressmakers in the city. In reporting these cases the *Belfast W* states that the sheriff regretted exceedingly that legislation o provided a fine of 40*s*. for so gross a crime against the pu interest. In the second case no comment seems to have b made and no doubt the sheriff felt the impossibility of doing so temperate language. In both instances the house was occupied several people. We share the sheriff's regret that the fine which Legislature has thought sufficient in these cases is so ridiculou inadequate and we have called attention to the matter on sev occasions, but until the law is altered and the penalty is m greater the public will still be exposed to the danger of infec through the criminal action of selfish or ignorant people.

THE writer of an account of a Case of Eclampsia, the manuscript which bears no title or author's name, is requested to communi with us.

THE writer of a letter signed "G.P." and dated Feb. 17th is also quested to communicate with us.

◆

*Neurin.*—Our correspondent is recommended to apply to Profe Adamkiewicz himself. His address is IV Wiedner Hauptstrasse Vienna, Austria.

*J. B.* should consult his medical man. We do not give medical adv

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthal (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and Central London Ophthalmic *Hospitals operations are performed dail* the fiftieth anniversary of the formation of the association. This conference will take place in the Town Hall, Manchester, on April 24th and 25th next. On April 24th the Bishop of Manchester, who is the President of the association and of the general conference committee, will deliver an inaugural address. Dr. Arthur Ransome, F.R.S., will then relate the interesting history of the Manchester and Salford Sanitary Association, and Sir James Crichton Browne, F.R.S., will follow with an address on Light and Sanitation. On April 25th Mrs. H. J. Tennant will speak on Women's Work in Sanitary Reform; Dr. Arthur Newsholme of Brighton will discourse on Vital Statistics and their Relation to Sanitary Reform; Mr. T. C. Horsfall, a local authority, will read a paper on the Housing Question; Sir William H. Broadbent will give an address on the Prevention of Tuberculosis; Dr. A. Bostock Hill of Birmingham will deal with the Relationship of Voluntary Effort to Constituted Authority in promoting Sanitary Reform; the Earl of Meath will speak on Physical Training; and Dr. J. Niven of Manchester will deal with the Economics of Health. Amongst others who will preside at meetings are Professor J. Dixon Mann, M.D. (the present chairman of the association), Sir William H. Houldsworth, Bart., M.P., Mrs. Moorhouse, Dr. Henry Simpson (a former chairman of the committee), Alderman Walton Smith, J.P. (chairman of the Sanitary Committee, Manchester), Mr. W. J. Crossley, J.P., C.C., Mr. A. Hopkinson, K.C., (Principal of Owens College), the Mayor of Salford, Sir J. T. Hibbert, K.C.B., and Councillor W. Huddart (chairman of the Salford Health Committee). Many municipalities, urban district councils, and other public bodies have appointed delegates or intimated that they will be otherwise represented. All local institutions having aims in common with the association are represented on the conference committee. The proceedings of the conference will be eventually printed and published.

### *Flannelette Test.*

At an inquest held at Southport on March 22nd, on a child who died from burns through its flannelette clothing catching fire, the coroner read a letter from a Manchester manufacturer protesting against the opinions of coroners on flannelette and inclosing a sample for testing. On putting a lighted match to it the sample would have been consumed quickly if the coroner had not blown it out, and he said: "With all due respect to the manufacturer I think it would be better not to continue the test."

March 24th.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

### *The Notification of Tuberculosis.*

IN some towns where phthisis is notified to the medical officers of health there appears to be a little doubt as to what subsequent action should be taken by the sanitary authority, and at a recent meeting of the South Wales branch of the Association for the Prevention of Tuberculosis the medical officer of health of Cardiff (Dr. E. Walford) suggested that female health visitors might very profitably be employed in this connexion, and it was decided to solicit the coöperation of nursing institutions and of voluntary workers.

### *A Medical Slander Action.*

At the Glamorganshire Assizes held at Cardiff on March 17th a medical man practising in Barry was the defendant in an action for slander and was ordered to pay £10 damages. The case arose out of the death of one of the defendant's patients who had been struck some time prior to his death by the plaintiff. The defendant attributed his patient's death to this blow and was said to have remarked to a friend when speaking of the affair, "It is a brutal murder." His own version of the expression used was, "It is a brutal matter." The smallness of the damages awarded makes it apparent that the jury were not very much impressed with the gravity of the slander.

### *Cardiff and County Public Health Laboratory.*

The Cardiff and County Public Health Laboratory was established about three years ago by the Glamorganshire County Council, and for the past two years has been under the joint control of the Cardiff Corporation and the county council. The second report of the bacteriologist (Dr. W. G. Savage) reveals the immense value such an institution must be to the sanitary authorities in the county. The water-supplies of Cardiff are now examined monthly and of many parts of the administrative county at fixed intervals. Altogether, 558 samples were examined during 1901. It is noticeable that there were 575 specimens for suspected diphtheria, tubercle, &c., from Cardiff examined bacteriologically and only 395 from the county, although the population of the latter is 600,000 and of Cardiff only 170,000. This disparity can hardly be due to the absence of material in the county, for diphtheria was excessively prevalent during the whole year in the large centres of population such as Merthyr and the Rhondda. In connexion with the laboratory, classes in bacteriology, chemistry, and practical outdoor sanitary work are held and were attended during 1901 by some half-dozen students.

### *Depopulation of Rural Districts.*

Most of those who have given the subject any serious consideration are agreed that the cramped and often dilapidated condition of the cottages in rural districts accounts in a great measure for the decrease in the population in those districts. The medical officer of health of the Gower peninsula in South Wales (Mr. H. E. Rawlings) in his annual report states that in his opinion if more cottages with small holdings were established it is practically certain that a large number of those who had emigrated to the towns in search of employment would return to the country to pursue a more healthy and congenial industry.

March 24th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *The John Usher Institute of Public Health, Edinburgh.—Arrangements for the Examination of Pathological Products for the City.*

THE John Usher Institute of Public Health, which is now almost completed, will probably be opened within the next three months. The chair of public health in Edinburgh University was founded in 1898—the necessary endowment having been provided by a legacy of £5000 from the late Mr. A. L. Bruce, supplemented by over £2000 from Mrs. A. L. Bruce and others, together with £8000 given by Sir John Usher of Norton. The Public Health Department in the new university did not, however, possess adequate laboratory accommodation for the new chair. Sir John Usher then most generously offered to build and to equip an Institute of Public Health, and it is this institute which is now nearing completion. It was at first intended that the building should occupy ground lying between the Music Class room and the Students' Union but this site had to be abandoned as the supply of light was deficient. A site in Warrender Park-road was then adopted, where the conditions as regards light-supply are all that could be desired. The institute lies on the south side of the road and faces north. It is rectangular in form and covers an area of 133 feet by 48 feet The exterior of the building is treated simply in classic Renaissance style. On the lintel of the main doorway three shields are to be cut, the centre one representing the Scottish Lion and the lateral shields showing the coat-of-arms of the donor, Sir John Usher, and of the Chancellor of the university, the Right Honourable A. J. Balfour. The coat-of-arms of the university will be carved on the pediment above the entrance. On the west front of the building the following inscription will be carved:—

University of Edinburgh.
The
John Usher Institute of Public Health,
Presented to the University of Edinburgh
by
Sir John Usher of Norton and Wells, Baronet.
May, MDCCCCII.

The ground floor contains entrance-hall, staircase, museum, research room, gas analysis and micro-photographic room, three laboratory workrooms designed for carrying on the bacteriological work in connexion with the public health administration of the city, two subsidiary workrooms, and caretaker's house. The first floor contains a chemical laboratory, balance room, optical room with adjoining dark room, students' reading room, water analysis room, research

## SOCIETIES

DNESDAY (2nd).—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Specimens will be shown by Dr. Fairbairn, Dr. Williamson, Dr. Berkeley, Dr. M. Kerr, and Dr. A. Routh, Paper.—Dr. Lewers: A Case of Primary Tuberculosis of the Cervix simulating Cancer and treated by Vaginal Hysterectomy.

HURSDAY (3rd).—RÖNTGEN SOCIETY (20, Hanover-square, W.).—8 30 P.M. Paper forwarded by Dr. Ch. Leonard (Philadelphia): X ray Diagnosis of Renal Calculus.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8 30 P.M. Paper:—Dr. R. Bowles: The Practical Treatment of Functional Vasomotor Disturbances.—Mr. R. Johnson: Some Points in the Treatment of Tuberculous Disease of the Knee.

DAY (4th).—WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—8 45 P.M. Discussion on Anæsthetics (introduced by Dr. B Gardiner).

ITISH ELECTRO-THERAPEUTIC SOCIETY (11, Chandos-street, Cavendish square, W).—8 30 P.M. Papers:—Dr. H. Walsham: The Diagnosis of Thoracic Aneurysm by the X-rays (illustrated by the lantern).—Dr. Sequeira: The Finsen Treatment of Lupus, Rodent Ulcer, &c. (illustrative cases will be in attendance at 8.15 P.M.).

EST LONDON MEDICO-CHIRURGICAL SOCIETY (Society's Rooms).—.30 P.M. Papers:—Dr. J. Allan: The Treatment of Malignant Disease by Electrical Currents of High Potential Frequency (with notes of cases).—Dr. A. Whitfield: A Case of Peculiar Intolerance of the External Application of Mercury.—Dr. J. D. Mortimer: Remarks on 1000 Anæsthetisations.

DAY (4th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. H. Tilley: Clinique. (Throat.)

## EDITORIAL NOTICES.

t is most important that communications relating to the torial business of THE LANCET should be addressed *usively* "TO THE EDITORS," and not in any case to any tleman who may be supposed to be connected with the orial staff. It is urgently necessary that attention be n to this notice.

*especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to his Office.*

*tures, original articles, and reports should be written on ne side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*ers, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*cannot prescribe or recommend practitioners.*

*al papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*ers relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*annot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

E Index to Vol. II. of 1901, which was completed with issue of Dec. 28th, and the Title-page to the Volume, given in THE LANCET of Jan 4th.

### VOLUMES AND CASES.

OLUMES for the second half of the year 1901 are now ly. Bound in cloth, gilt lettered, price 18s., carriage a.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 12 6 | One Year ... ... ... | £1 14 8 |
| Six Months ... ... .. | 0 16 3 | Six Months ... ... ... | 0 17 4 |
| Three Months ... ... | 0 8 2 | Three Months ... ... | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

**During the week marked copies of the following newspapers have been received:**—*Eastern Evening News, Army and Navy Gazette, Clinical Journal, Nursing Record, Sanitary Record, The Rock, Nordiskt Medicinskt Arkiv, Wolverhampton and Coventry News, Middlesboro Daily Gazette, Warwick and Warwickshire Advertiser, Wynberg Times, Reading Mercury and Oxford Gazette, Western Morning News, Echo, Glasgow Evening News, Surrey Herald, Manchester Guardian, Morning Leader, Star, South Wales Daily News, Standard, Freeman's Journal, Birmingham Post, South Wales Echo, Birmingham Mail, Hartlepool Mail, City Press, Tunbridge Wells Advertiser, &c.*

room, cloak room, and lecture theatre, with adjoining preparation room. Under the staging of the lecture theatre are store-rooms for apparatus, &c. On the second floor there are a bacteriological laboratory, research room, observation room, disinfection room, two incubation rooms, small lecture room for advanced class, professor's laboratory, retiring room, and library and assistant's room. In the upper storey are placed the extraction ventilation chambers and on the roof provision has been made for carrying out experiments in the open air. In the basement floor there are a refrigerating room, an incinerating room, a room containing a large centrifugal machine with electric motor, and a room for air and water pressure apparatus. Needless to say, the internal arrangements and fittings of the museum and of the various laboratories are of the most approved and up-to-date description. In giving the institute to the university Sir John Usher made the request that the University Court should provide accommodation for carrying out scientific work in connexion with the public health administration of the city. The committee of the institute accordingly set apart the three rooms above-mentioned on the ground floor of the institute for that purpose, and since 1898 has been carrying on negotiations with the town council in connexion with the matter. The Public Health Committee of the town council was not in favour of handing over the bacteriological work of the city to the Usher Institute, and a fortnight ago reported to the town council on the subject, recommending that the work should not in the meantime be taken from the laboratory of the Royal College of Physicians of Edinburgh, where it was being done in a perfectly satisfactory manner. The town council, however, refused to adopt this report and accepted the proposals of the committee of the Usher Institute. Put as briefly as possible those proposals are: 1. That the three rooms above-mentioned be entirely set apart for the city's work. 2. That a qualified assistant be appointed who shall attend exclusively to the city's work and that the services of an attendant be available. 3. That the whole work be done under the supervision of the professor of public health who shall alone be responsible to the city for the work. 4. The scope of the work to be as follows: (1) bacteriological examinations required by the medical officer of health in the daily work of dealing with infectious disease; (2) bacteriological examinations required by the sanitary inspector (these would include examinations of water, milk, food-stuffs, and flesh, and would also include examination for anthrax and glanders), and (3) bacteriological examinations of specimens in cases of diphtheria, typhoid fever, and tuberculous disease which may be sent by medical practitioners in the city for diagnostic purposes. 5 That the university agrees to perform the whole work for the outlay incurred. The committee estimates that for the investigation of 1000 specimens the cost will be about £360 per annum, this being founded on the experience of cities where a similar arrangement prevails. Of the three rooms mentioned two will be fitted with laboratories, while the third will be used for clerical work. In this third room the samples for examination will be received, the result of the examination recorded, and the reports of the results sent to the medical officer of health or to the practitioner, as the case may be. It is expected that the institute will be opened in May by the Chancellor of the university, the Right Hon A. J. Balfour, M.P.

### *Aberdeen University.*

The Aberdeen University Court met on March 11th. The secretary read a letter from the Baroness de Gurbs, intimating her desire to place a stained-glass window in King's College Chapel as a memorial of her late husband, Stephen Baron de Gurbs, a former student of Aberdeen University. It was agreed that the offer should be accepted.—It was agreed to appoint Mr. Charles Murray, M.A., M.B. Aberd., to the post of university assistant in physiology, vacant through a resignation.

March 24th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Public Health of Dublin.*

THE fortnightly meeting of the Public Health Committee was held in the Municipal Buildings on March 18th, when Sir Charles Cameron reported that the death-rate from all causes in the city for the week ending March 15th was 22·2 per 10,000 persons living. This rate, he observed, was unprecedentedly low for this time of the year, the mean for the last 10 years being 34·1. The zymotic death-rate for the suburbs proved to be unusually high—namely, three per 1000, or six times that of the city.

### *Surgeon-Captain Crean, V.C.*

The Royal College of Surgeons in Ireland has decided to confer the honorary Fellowship on Surgeon Captain T. J. Crean, V.C., in recognition of his distinguished services in South Africa. He commenced his medical studies in the College School and obtained the Licence of the College in 1895. Since the institution of the reward for "conspicuous valour in the presence of the enemy" five Irish surgeons have been awarded the Victoria Cross. Of these, one belongs to the University of Dublin, while the other four are Licentiates of the Royal College of Surgeons in Ireland.

### *An Isolation Hospital for Kingstown.*

A special meeting of the Kingstown Urban District Council was held on March 21st in the Town Hall, Kingstown, to deal with the question of a proposed isolation hospital for the township. After a lively discussion the matter was practically shelved. Mr. D. Edgar Flinn, the medical inspector of the Local Government Board, who was present, intervened, and addressing the council said that in postponing this question it had incurred a very serious responsibility by taking no steps in reference to the treatment of infectious diseases. He pointed out that the council was the custodian of the public health of the most important watering-place in Ireland, in touch with the other side of the Channel where small-pox was now epidemic. He stated that he was there at the request of the Local Government Board to convey to the council their desire that arrangements should be made for the treatment of infective diseases and to state that a temporary isolation hospital could be erected in a fortnight. Rathmines and Pembroke districts were constructing a temporary isolation hospital and such buildings were being erected all over the three kingdoms. If a case of small-pox occurred where was it to be sent? None of the Dublin institutions would admit the patient. This postponement, he said, might mean a very serious matter for the council and the responsibility was on its shoulders and not on those of the Local Government Board. At the conclusion of the meeting it was arranged that Mr. Flinn should attend the proposed meeting of the Sanitary Committee of the council.

March 24th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *The Plague.*

I HAVE on previous occasions[1] given your readers information about sundry cases of plague which occurred last year on board the *Sénégal* and about the complaints made concerning the Frioul lazaretto. The Academy of Medicine which was very anxious to find the best means of prophylaxis against the plague appointed a committee of inquiry with a view to the reform of the French sanitary service. Dr. Vallin, the secretary, made a minute investigation of the Frioul lazaretto on behalf of the committee and his report thereon was submitted to the Academy of Medicine at the meeting held on March 11th Dr. Vallin insists on the reorganisation of the lazaretto at Frioul. There should be a medical director serving immediately under the Minister of the Interior and a sanitary station ought to be erected at the north-east point of the island of Pomègues which should be independent of the lazaretto. Quarantine for passengers should be given up but they should be compelled to be inoculated with anti-plague serum. The report suggests that the Minister of Marine should be asked to make the carriage of anti-plague serum and the instruments necessary for its administration obligatory on all merchant ships which take long voyages. The inspection of ships' medicine chests and dispensaries should be much more strict and such should be passed by the port sanitary authorities. All rats on board a ship coming from an infected port should be destroyed. Facilities should be given to

medical men who may be candidates for employment in the maritime sanitary service for study at a port school of medicine so that they could acquire special professional knowledge which should be tested by examination. Finally, medical men in the service of steamship companies should be given an independent position, so that they should no longer, as is the case at present, be in the position of having to make the performance of their duty stand out in opposition to their chances of security of tenure.

### *The Inability of Medical Men to Inherit from Patients.*

It is well known that neither medical men nor pharmaceutical chemists in France have any legal right to receive a legacy from their patients or customers. Dr. Delarue brought before the Chamber of Deputies on Feb. 21st a proposed alteration in the law which ran as follows: "The incapacity laid down by Article 909 of the Civil Code is henceforward abrogated as far as concerns physicians, surgeons, and apothecaries." It is extremely improbable that the Chamber will pass this alteration in the law, despite the very serious reasons which exist in favour of such alteration and which were put forward by Dr. Delarue. Very often, he said, the medical man was exposed to the risk of serious illness or even of death and had to be contented with very poor pay, and, in fact, more often than not the only reward he gained by his profession was the consciousness of duty done. His devotion was always being appealed to and such appeal was never unheard. If the medical man were always to demand remuneration for his work it would be impossible to make certain that the hospital service should be carried on or that the regulations of the Assistance Publique should be duly complied with. Official salaries were increasing and also retiring pensions but there was nothing to help an old physician who had devoted perhaps 40 years of his life in the service of his equals. Moreover, the law as it existed at present did the medical men the injustice of apparently suspecting every medical man to be capable of abusing the power which he possessed over his patients for the purpose of getting hold of their money and of making them carry out their last wills and testaments in opposition to their own wishes. Why did not the law inflict the same disabilities on other professional men, such as barristers or solicitors who had just as much influence over their clients as medical men had over their patients. There was no good explanation why medical men should be thus treated. As for apothecaries, they had nothing to do with the treatment of patients, for their only duty was to send in medicine prescribed by the medical man.

### *Photo-therapy and the Iron Electric Arc.*

On March 3rd M. A. Broca and M. Chatin laid before the Academy of Sciences the results of their attempt to utilise an iron electric arc in photo-therapy. They have managed to obtain a perfectly steady arc which takes a current of from 10 to 30 ampères. This arc is very rich in actinic rays which are alone of use. Exposure to it for five seconds reduces ordinary silver photographic paper to a deep red-violet colour. Moreover, it gives hardly any heat rays and so the patient can be placed within 10 centimetres of the apparatus, while the need for a cooling jacket is done away with. The simplification of the apparatus allows of much more exact compression of the affected region being employed than has hitherto been the case with other apparatus, and M. Broca and M. Chatin have used the process at the St. Louis Hospital in nine cases of lupus with excellent results. The arc is covered by a metallic sleeve with a hole of three centimetres in diameter opposite the patient, so that the assistants are completely protected. With an iron arc taking from 15 to 18 ampères and an exposure of from 19 to 25 minutes very remarkable cutaneous reactions were produced in all the patients. They appeared from some 24 to 48 hours after the exposure. Phlyctenulæ comparable to those seen after the use of the Finsen and similar apparatus were noticed, but the light rays appeared to exercise a selective influence on the lupus nodules which were profoundly affected, although the periphery of the ulcer and the healthy skin only showed a slight raising of the epidermis. These results would seem to foreshadow a great future for this method which in addition to giving rays of increased actinic power enables photo-therapy to be carried out without the use of the cooling apparatus which, besides being very complicated, absorbs a certain amount of light rays.

### *Action against the Director of a Lazaretto.*

A curious case is now before the courts. Last year a ship arrived from Brazil at Bordeaux on board of which was a young woman far advanced in pregnancy whom the medical officer of the lazaretto compelled to disembark as he suspected that she was suffering from yellow fever. Within a few hours she died and was hurriedly buried. The husband hastened to the spot and, having obtained an exhumation order, found not only the body of his wife but also that of an infant lying between her legs. Now he has haled the medical officer before the courts, declaring that his wife was not suffering from yellow fever but only from troubles incidental to pregnancy. He further declares that she was buried alive and that the birth of the child followed spontaneously on the burial. So, then, this case raises a curious point in obstetrics as well as the question of the responsibility of medical officers of lazarettos.

March 24th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *Bacilli in the Seminal Fluid in Syphilis.*

AT the last meeting of the Berlin Medical Society Dr. Joseph and Dr. Piorkowsky showed specimens of bacilli discovered by them in cases of syphilis. They examined the semen of syphilitic persons, because in many instances a man without manifest symptoms of syphilis has been known to communicate the virus to a healthy woman by way of the placenta, the effect being that she does not exhibit evidence of the disease until she becomes pregnant. They described their procedure as follows. Semen was obtained from 22 men who had contracted syphilis at different periods varying from five weeks to two years previously and was placed in contact with sterilised pieces of placenta, on which as a nutrient medium there was an abundant bacterial growth, containing after 12 hours long bacilli with clubbed ends resembling those of diphtheria. Cultures transferred from the pieces of placenta could be grown upon agar and blood serum, but direct inoculation of the semen upon agar without previous use of placenta gave no result. The colonies growing on agar developed very quickly but soon showed signs of degeneration which could be made to disappear by reinoculation of the cultures on placenta. The bacilli were stained by Gram's method and could be agglutinated by serum. In five cases of syphilis which had lasted for periods varying from three to 10 years the results were negative. The bacilli were not present either in normal semen or in cases of azoöspermia occurring in syphilitic men. Inoculation into animals gave no decided result. A pig after inoculation developed a peculiar exanthem on the genital organs together with a swelling of the lymphatic glands, but as it died six days later from an epizoic malady these symptoms might perhaps have been due to the latter cause. Dr. Joseph was of opinion that the bacilli discovered by him were specific for syphilis but further investigation on a larger scale was necessary. In the ensuing discussion Professor Jürgens of the Pathological Institute said that similar bacilli had already been described by Dr. Von Nissen. He pointed out that in one of the specimens there were no bacilli but there were spores, so that a mixed infection had perhaps occurred. He recommended that cases of congenital syphilis should be included in the observations, because in them it was possible to avoid mixed infections. Dr. Aronson said that chronic diseases were usually of slow development and considering the rapid growth of Dr. Joseph's bacilli it was unlikely that they were the cause of so chronic a disease as syphilis. Dr. Joseph, in his reply, said that as regards the bacterial origin of syphilis he had been careful to speak with all reserve but he thought it right to mention that the bacilli in question had never been found in normal semen.

### *Medical Experts in the Law Courts.*

The trial of Professor Dührssen, of which an account appeared in THE LANCET of March 15th, 1902, p. 779, has directed attention to the state of the law relative to medical evidence given before courts of justice. As a general rule the medical officer of health of the district is *ex officio* medical expert in the courts but in some of the larger towns special medical officers have been appointed for this duty. In cases of considerable importance and in appeal cases recourse is had to the provincial board which exists in each province (Provincial Medicinal-Collegium) composed of professors of the university of the province together with Government medical officers and others, and to a central board in Berlin (Wissenschaftliche Deputation für das

Medicinalwesen) composed of professors of Berlin University only. The professional opinions given by the authority last named have a great influence on the decisions of the courts, for the judges believe that no expert is more competent in medical questions than this board and its opinion is very seldom disregarded. Since the Dührssen trial, however, some medical journals have pointed out that although the board is composed of the leading medical men of Berlin its formally expressed opinions nevertheless do not possess the weight and importance with which they are usually credited When in a given case the opinion of the board is asked by a public prosecutor or by a court of justice the president of the board, as a rule, entrusts the matter to a member who is a specialist in that department. If, for instance, a surgical case is under consideration it is one of the surgeons or if it is a gynæcological case it is the gynæcologist who draws up the report. There is no discussion of the matter by the whole board; when the report is prepared it is signed by the other members but in reality the opinion of the board is only the opinion of one member whose views may sometimes be out of date and who is by no means superior to other specialists who may be called by the other side. Moreover, the opinion of the board or of the member who acts in its name has to be based on written statements, for the patient is very seldom examined with a view to the preparation of the report. It is also quite unusual for members of the boards to attend a court as witnesses or to undergo cross-examination; a member of the provincial board was present at the trial of Professor Dührssen but the central board was not represented at all. Some medical journals now propose that this system should be altered by abolishing the boards and that in cases of considerable importance the opinions of the most competent men in the respective branches of medicine should be asked, as they would be required to appear in court and after being sworn as experts might be cross-examined like other witnesses.

### *The Congress of Naturalists and Medical Men.*

The seventy-fourth congress of the German Association of Naturalists and Medical Men will this year be held beyond the borders of the German Empire—namely, in Carlsbad, the famous mineral water resort in the Austrian province of Bohemia. The congress will meet in two principal sections—a medical one with 17 subdivisions and a scientific one with 11 subdivisions. The medical subdivisions are as follows: (1) anatomy, histology, and physiology; (2) general pathology and pathological anatomy; (3) clinical medicine, pharmacology, balneology, and hydrotherapeutics; (4) history of medicine; (5) surgery; (6) obstetrics and diseases of women; (7) diseases of children; (8) nervous and mental diseases; (9) ophthalmology; (10) diseases of the larynx, nose, and ear; (11) dermatology and syphilis; (12) odontology; (13) military medicine; (14) forensic medicine; (15) hygiene; (16) veterinary medicine; and (17) pharmacy. In the medical section the official subject of discussion will be physiological albuminuria and in the scientific section it will be the circulation of nitrogen.

### *"Christian Science."*

The fantastic doctrines known by the name of "Christian science," with which the name of Mrs. Eddy is associated, continue to occupy the attention of the public, and it is said that they have made more progress, especially among females, than is generally supposed. Believers abound in Potsdam, where the Emperor's summer residence is situated, and many of the nobility and court officials engage in the exercises prescribed by Mrs. Eddy. The Emperor has expressed strong disapproval of these proceedings, and has caused it to be announced that persons who attend the meetings or in any other way encourage the new system will not be admitted to Court.

March 24th.

**THE EXAMINER IN PHYSICS AT EDINBURGH UNIVERSITY.**—The Edinburgh University Court, which met on March 17th, appointed Mr. Dawson F. D. Turner, M.D., F.R C.P. Edin., examiner in Experimental Physics to the University. We believe that this university is the first to have recognised the importance of having an examiner who has received a medical training to examine medical students in physics.

# Obituary.

## WILLIAM TOWLSON KAY, M.R.C.S. ENG., L.R.C.P. EDIN.

THE death is announced of Mr. W. Towlson Kay, late of Gateshead, which occurred at Eastbourne on March 9th. Mr. Kay was born in 1849 and was a student at the Newcastle-on-Tyne College of Medicine, where he had a distinguished career. After securing his diplomas he was appointed medical tutor to his college for a time when he joined the late Dr. Dixon of Gateshead in partnership. Later he practised on his own account and soon secured a large and good practice. He was appointed surgeon to the Gateshead police, a post which he held for 25 years. Three or four years ago his health began to fail and in October, 1900, he retired from practice and went to live at Eastbourne. For a time his health improved but in the autumn of last year he had a relapse which ended fatally on March 9th. Mr. Kay was a great favourite with his patients owing to his genial manner and assiduous attention to them. He took no part in public life but was a member of the local medical societies. He leaves a widow but no children.

## JOHN BARCLAY, M.D., C.M. ABERD.

DR. BARCLAY of Banff died at his residence there on March 11th, after a lingering illness. He received his medical education at the University of Aberdeen, where he graduated in 1862, and was then appointed assistant professor of materia medica and medical jurisprudence. 30 years ago he commenced practice in Banff and built up one of the largest medical practices in the county of that name. He held many public and official appointments in Banff. Dr. Barclay acted as an examiner at Aberdeen University from 1880 to 1883. His wife, who was a daughter of the late Provost Coutts of Banff, predeceased him several years ago. He leaves two sons and two daughters.

## HUGH FRASER, M.B., C.M. ABERD.

A CABLEGRAM was received in Aberdeen on March 11th stating that Dr. Hugh Fraser had died from enteric fever at Bethulie, South Africa, on March 4th. After graduating at Aberdeen University Dr. Fraser came to England, and some four years ago he proceeded to King Williamstown, Cape Colony, where he was stationed until a few months ago, when he accepted the position of medical officer in the camp at Bethulie. Dr. Fraser was the youngest son of the late Dr. George Innes Fraser of Aberdeen. The deepest sympathy is felt for Dr. Fraser's mother in her sudden and unexpected bereavement.

# Medical News.

**SOCIETY OF APOTHECARIES OF LONDON.**—In March the following candidates passed in the subjects indicated:—

*Surgery.*—C. R. Bradley (Section I.), St. George's Hospital; S. J. H. M. Eastwick Field, Royal Free Hospital; J. W. Elliott (Section I.), St. Mary's Hospital; H. S. French (Sections I. and II.), Oxford and Guy's Hospital; E. O. Libbey, Leeds; K. Heanley (Section I.), Royal Free Hospital; and S. C. Wilkinson (Sections I. and II.), Leeds.

*Medicine.*—F. G. Bennett (Section II.), University College Hospital; W. T. Colyer, Cambridge; H. S. French (Sections I. and II.), Oxford and Guy's Hospital; R. Gauld (Sections I. and II.), London Hospital; K. Heanley (Section I.), Royal Free Hospital; W. St. A. F Hubbard (Sections I. and II.), Charing Cross Hospital; O. Millauro (Section I.), Westminster Hospital; H. H. Sloane (Section II.), St. Bartholomew's Hospital; W. P. Taylor, Sheffield and Bristol; J. E. Turle (Section I.), University College Hospital; and A. F. Van Dijk (Sections I. and II.), St. Bartholomew's Hospital.

*Forensic Medicine.*—H. S. French, Oxford and Guy's Hospital; W. St. A. F. Hubbard, Charing Cross Hospital; W. P. Taylor, Sheffield and Bristol; J. E. Turle, University College Hospital; A. F. Van Dijk, St. Bartholomew's Hospital; and J. H. Williams, London Hospital.

the much longer time which contracture takes to develop in this disease.

3 Little's disease which is also known as "congenital spastic paraplegia." The involvement of the lower extremities and the etiology of the two diseases are sufficient for a diagnosis, which must be obvious to anyone.

4. Functional disease. I saw one case of Volkmann's contracture diagnosed as "functional." No doubt the mistake arose as it generally does: if we see any disease which we cannot diagnose the temptation is to call it functional. The absence of any serious injury, the greater age of the patient, while the hand will possibly be contracted as well as the fingers atypically form the points of diagnosis. The complete reduction of the contracture under an anæsthetic will be proof positive of functional disease. The electrical reactions in each case will be normal. There are a few other cases which are certainly worth recording here (1) In the case of a patient under the care of the late Mr. William Anderson[25] who was bitten in the forearm by an adder the injury was followed by pain and swelling accompanied by a painful contraction of the fingers which lasted nearly three months; it was ultimately relieved by massage and active and passive movements. In giving the pathology of this condition Mr. Anderson remarks that it was "due to diffuse inflammation of the inter-muscular planes and perimysial connective tissue; that it may occur as a result of poisoned wounds and other injuries, sometimes leading to a deformity in the fingers, as is met with in ischæmic paralysis." (2) König (quoted by Anderson) describes a case of flexion of the hand and fingers in a newly-born child caused by a tearing of the flexor muscles at the moment of disengagement of the arms in the course of delivery. Lastly, Dr. Turney tells me of a case which he saw in consultation where there was no contraction of the hand and fingers but great wasting of the muscles of the forearm. At first sight, when he saw the case, he thought that it was due to nerve injury, but he found the electrical reaction quite normal and the flexor muscle of the forearm firm and hard. Two scars showing past pressure sores were also present. The reason of the absence of deformity was due to the fact that the patient had always worn a splint reaching to the tip of the fingers.

*Prognosis.*—Volkmann makes this statement: "The prognosis is bad, especially in cases where the hand and fingers are affected; here it is practically hopeless. It is better in the lower limbs, for here tenotomy may be practised; slighter cases may be improved with massage." In 1891, or about 10 years after Volkmann's paper, Mr. Anderson gave a prognosis absolutely contradictory to Volkmann. He says: "The lesion—i.e., ischæmic myositis—is seldom of a permanent character and the function may generally be restored by systematic active and passive movements with massage and, if necessary, the galvanic current." He gives no cases to substantiate his statement and there is certainly nothing in the literature that I can find so completely to oppose Volkmann's gloomy prognosis. When, however, one refers to the cases which I have published it will be seen that the prognosis given by Mr. Anderson is exactly in accordance with these results. I think that I am right in stating that the patients in Table I., when they left St. Thomas's Hospital with complete deformity of the hand and forearm, were not expected in two or three years to obtain a normal arm, but such is the case. When I received letters replying to my question from two different patients stating that they had completely recovered I could not understand it, but it was quite obvious when I saw the cases. Surgical methods of lengthening tendons, shortening bones, &c., cannot produce with the very best results possible a better condition of affairs than I now publish. Of course, one cannot be absolutely certain that so happy a result would always ensue, but still these are not selected cases, but those which Dr. Turney had seen in the hospital and which had been diagnosed by him as ischæmic myositis. I cannot say whether the fact of having normal electrical reaction—as all the cases I reported had and have—may be such an advantage as to give recovery by simple massage, &c.

*Treatment.*—In his Hunterian Lecture of 1891 the late Mr. William Anderson stated that "ischæmic paralysis is a reproach to surgery, since a careful observation of the hand and fingers during the use of splints will always give due warning of the danger." The only objection to this statement is when the deformity arises from other causes than bad treatment, as it undoubtedly may do, Mr. Littlewood holds the view that splint pressure has nothing to do with the production of the deformity. This statement is going to the other extreme and is certainly incorrect in many cases. There is no better illustration than Case 4 of my series, where there was a severe injury with a large amount of swelling. "Plaster splints" were applied to the forearm; this was followed in 24 hours by swelling and duskiness of the fingers, paralysis, and contracture, with a pressure sore besides. This is one example out of many. Therefore in a severe injury to the bones of the forearm and lower end of the humerus it seems obvious that anterior and posterior splints should not be applied, or at any rate not in these cases when there is much swelling, and several surgeons, notably Mr. Page, disagree with the use of splints. When the contracture has occurred and is of recent origin Volkmann recommends the extension of the muscles under an anæsthetic. This treatment alone has proved to be valueless, and the extension of the muscles is no easy matter; the contracture still continues till it reaches a maximum even under extension. There seem to be two methods of treatment, medical and surgical. The former consists of massage to the forearm twice daily for 10 minutes or more (as long as there is no pain) and passive movements of the fingers. The galvanic current can be given, but I do not think it would make any difference. This treatment must, no doubt, be carried on without any long interim for about two years to have the complete results here shown, as it took quite that time in both my cases to effect complete cure. The results of this treatment have already been discussed and show what great value it has. Massage in each case was performed by the friends and has given as good a result as any professional expert could possibly obtain, and with this advantage for hospital patients especially—it was performed free of charge.

As to surgical treatment and the time of operation, as many of the cases slowly continue to contract for some time after the accident it seems possible that it would be better to delay operation for three or four months. The different operations which have been performed are numerous. Mr Davies-Colley cut through the flexor muscles of the forearm themselves, and at a second operation, a month after, cut through all the flexor tendons. The deformity is certainly cured by such treatment, but no hope of flexion of the fingers can ever be entertained. Mr. Raymond Johnson excised a short piece of bone from the middle of the shaft of the radius and ulna. The effect on the contracted wrist and fingers was satisfactory, but the divided bones only united by fibrous tissue and the child had to wear a leather splint. This case was shown at a meeting of the Harveian Society of London on March 3rd, 1898. Mr. Edmund Owen who discussed the treatment of such cases advised resection of bone, but stated that surgeons must be prepared for the result of non-union of the divided bone, but he gave no proof for such a statement. Tendon lengthening, first advised in these cases by Mr. Page,[26] has since been carried out by Mr. Littlewood,[27] Mr. Barnard,[28] and others. It simply consists in splitting longitudinally the flexor tendons of the fingers or cutting them in a Z-shaped fashion, then when full extension has been applied suturing the lengthened ends. The after-treatment consists of keeping the hand and fingers on a splint for about a fortnight, then gradually applying massage, the galvanic current, and finally by active and passive movements of the fingers, hand, and forearm. Lastly, in cases where the presence of a lump situated at the lower end of the humerus after an injury to the bone interferes with flexion and extension of the forearm this bony mass can be excised. This was done in Case 2 by the late Mr. Pollock with excellent results.

In conclusion, my best thanks are due to Dr. Turney for allowing me to use the cases which have been, or are at present, under his care in the electrical department at St. Thomas's Hospital, and also for much valuable advice in the study of this interesting deformity. I have also to thank Mr. Clutton and Mr. Pitts, as the cases which I report had originally been under their care.

St. Thomas's Hospital.

[12] St. Thomas's Hospital Records, 1896; also Transactions of the Clinical Society of London, vol. xxix, p. 241. [13] Loc. cit. [14] THE LANCET, Feb. 3rd, 1900, p. 291. [15] Loc. cit

different observers and commence by giving that of the eminent German surgeon who first described the disease. Volkmann considers that the paralysis and contracture are dependent on the diminution of arterial blood to the muscles—i.e., are ischæmic in origin—(see Case 14) whilst the simultaneous venous congestion which often takes place hastens the onset of the paralysis; the muscle fibres, being deprived of their oxygen for some time, perish; and the contractile substance coagulates, breaks up, and disappears—that is to say, *rigor mortis*. The rigidity and contracture of the limbs are made worse by the material contracting, which was present for the process of repair. The degree of paralysis and contracture depend on the length of time the circulation of the blood has been arrested. If the anæmia has been very marked the most serious results may happen in 12 hours or less. A slight but prolonged constriction and pressure of a limb may cause symptoms of great severity, especially in fractures of the radius. The late Mr. Davies-Colley[17] believed that this deformity is due to splint pressure on the skin causing inflammation which spreads to the muscles; or suppuration of all the soft parts may be got, the resulting fibrous tissue which contracts and gives rise to the deformity being formed from the granulation tissue of the soft parts. Mr. Raymond Johnson[18] considers that the "paralysis" is dependent upon inflammation and subsequent fibrous degeneration of the muscles caused by the application of splints sufficiently tightly to interfere seriously with the circulation through the part. Mr. Wallis[19] describes how this deformity of muscle is produced by Esmarch's bandage: "There is after removal of the bandage excessive capillary hæmorrhage; it occurs not only in the skin but also in the muscles There is no actual blood extravasated, but a large quantity of serum, and with it fibrous tissue-forming elements which escape into and around the tissues Thus the muscular fibres all become infiltrated with fibro-blastic elements, and eventually the healthy contractile muscle becomes largely mixed with fibrous tissue, and according to the amount of this tissue so contraction occurs. Ziegler[20] describes a form of myositis due to the extension of inflammation from the skin or elsewhere manifested by infiltration of the perimysium with liquid and accumulation of round cells into the connective tissue. The muscle fibres often remain intact throughout; when they also suffer cloudy swelling, fatty degeneration, and coagulation necrosis make their appearance. The deformity has been likened by some writers to congenital hæmatoma of the sterno-mastoid producing wry neck. Mr. Clutton[21] says: "Violence is the main cause of tumour of the sterno-mastoid" Dr. Spencer, quoted by Mr. D'Arcy Power,[22] proves beyond doubt that the cause of the condition is injury resulting in rupture of the fibres of the sterno-mastoid, with effusion of blood into the connective tissue. In other cases there is no doubt that inflammation alone may cause the tumour of the muscle But while, on the one hand, contracture is the rule in ischæmic myositis, it is far less common in congenital hæmatoma of the sterno-mastoid. Mr. D'Arcy Power gives 30 cases, traced by Mr. Clutton, himself, and others, of congenital hæmatoma, of which 11 eventually had wry-neck, but in two of these the deformity was very slight; it will thus be seen that there is a great difference between the injury and its result in the two deformities in question. Kraske[23] has shown that long-continued and severe cold may produce this deformity. Lastly, it seems to me that possibly, as so many of these cases commence as injuries in the region of the elbow-joint, the synovial membrane might be lacerated and the escape of the contained fluid with possibly some blood around the seat of the injury might help, or even entirely produce, this deformity in some cases. While discussing the pathology of this deformity I will add the condition of the muscles when examined by surgeons at operations. There are five reports in all, and every observer agrees that the muscles are wasted, pale, firm, and dry, and that they seem to be chiefly composed of fibrous tissue.

*Diagnosis.*—The diagnosis is usually easy, but still there are difficulties at times, chiefly in finding out whether the case is purely ischæmic myositis or whether it is this disease together with injuries of the peripheral nerves. In looking through the literature of the subject I find a large number of deformities which have entered into the diagnosis at some time or other. I think it therefore advisable to mention these and their diagnostic features. A case of Volkmann's contracture gives the history of a severe injury usually in the region of the elbow-joint or forearm accompanied by a large amount of swelling of the soft parts. The patient is usually a child (every patient in Table I. and in Table II. was under the age of 10 years, except in three instances, and two of these could hardly be included, as in one it was due to Esmarch's bandage and in the other to thrombosis of the axillary artery, and therefore they did not present the usual history). Splints have generally been applied and the contracture of the fingers has come on rapidly. This point, Volkmann[24] lays great stress on and says: "The paralysis and contracture arise simultaneously, not as in paralysis of nervous origin, where contraction is a later phenomenon and of gradual onset" A child presenting such a history as this and with the deformity of the hand as described in the paragraph on the symptoms, as well as with normal electrical reactions, is diagnostic of Volkmann's contracture.

We must now consider what other conditions produce such a deformity. I find that the following is a list of nerve lesions which are given as offering points of diagnosis: (1) ulnar, median, or muscular spiral paralysis; (2) the contraction after acute anterior poliomyelitis; (3) Little's disease; and (4) functional disease. The peripheral nerve palsies are alone worth considering fully; in the others the diagnosis is so obvious that a brief account is sufficient

1. In ulnar paralysis the paralysis generally comes on rapidly after wounds of the arm. The fingers cannot be flexed at the first joint or extended at the other joints. Adduction of the thumb is lost and so are most movements of the little finger. Anæsthesia occurs in most cases, corresponding with the inner side of the hand, the little finger, and the inner half of the ring finger The reaction of degeneration in the wasted ulnar muscles is present, but no reaction to stimulation of the ulnar nerve with the faradic current After a long period the "claw hand" is developed. There will be no contraction of the wrist. The hypothenar eminence may disappear The palm is hollow and trophic changes may be present. Therefore the points of diagnosis are many and should not offer much difficulty. In median nerve palsy there is paralysis of pronation beyond the mid-position; the thumb is extended and adducted The fingers are not contracted. There is little power to flex the wrist. Electrical reactions show reaction of degeneration in the affected muscles. Anæsthesia corresponding to the radial side of the palm, the front of the thumb, the first two fingers and half the third, and in some cases the back of the last phalanx of the index and middle finger. Trophic lesions may be present. In this palsy it is quite obvious that there is little resemblance to Volkmann's contracture. In musculo-spiral palsy, although there is dropping of the wrist, it is due to paralysis of the extensor muscles, not due to contraction of the flexors, as in Volkmann's contracture. The fingers are frequently in the position pointed out by Sir William Gowers, the first finger being least and the fourth most affected, thus showing a simple gradation. A very large number of the musculo-spiral palsies which come to the electrical department at St. Thomas's Hospital show this feature. The palsy may be bilateral, as it is usually in lead. The involvement of the triceps and supinator longus in some cases, with the well-marked reaction of degeneration in the affected muscles and the loss of sensation which sometimes occurs, is sufficiently characteristic for a correct diagnosis. Although these points are sufficient for diagnosis between the deformity in question and peripheral nerve palsy, yet it is highly probable that the nerves are also affected in some of the cases of Volkmann's contracture. For instance, we see in some of the cases reported loss of sensation corresponding to definite nerve areas, while in others there have been trophic ulcers The reaction of degeneration in the affected muscles in four cases out of five in which it was examined for in Table II is very important, while in Table I. in no case was it present I think therefore that the electrical reactions show quite clearly that there is, on the one hand, pure ischæmic myositis, with normal reaction; and, on the other hand, ischæmic myositis plus peripheral nerve palsy, producing complete or partial reaction of degeneration.

2 The contracture after the acute anterior poliomyelitis. If any history can be obtained of the onset of the case in question it will be practically sufficient for a correct diagnosis, although acute anterior poliomyelitis may follow directly after an accident, such as a fall, but the injury in no way resembles that met with in Volkmann's contracture. Also the far greater frequency of the involvement of the upper extremity (I can find only one case of Volkmann's deformity in the leg), and the reaction of degeneration in the affected muscles. Perhaps the most diagnostic point is

experiment. There are certainly those who are so susceptible as to require revaccination after six or seven years. It is much to be desired that those who have the cause of vaccination at heart should record statistics of this kind, as there appears to me to be a dearth of accurate information on this important subject. This is my only excuse for recording the facts above.

St. Bartholomew's Hospital, E C.

# A HISTORY OF THE AFTER-PROGRESS OF FIVE CASES OF PARTIAL GASTRECTOMY FOR CANCER OF THE PYLORUS.[1]

BY J. RUTHERFORD MORISON, M.B. EDIN., F.R.C.S. ENG. AND EDIN.,
SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

CASE 1.—The patient was a woman, aged 40 years. For five months previously to the operation she had pain after food and for two months she had vomiting. On her admission into the Newcastle Royal Infirmary she was confined to bed from weakness and was much emaciated. A freely moveable tumour of the size of a Tangerine orange was found under the umbilicus. Pylorectomy was performed on Oct. 21st, 1897.

From the time the patient left the hospital she was perfectly well until May, 1900. She was able to eat and to digest any ordinary food and worked regularly at her household duties. On Nov. 13th, 1897, she weighed six stones eight pounds and on Dec. 31st, seven stones nine pounds; on Feb. 11th, 1898, seven stones 13½ pounds; on Dec. 9th, 1898, eight stones three pounds; and on March 3rd, 1899, seven stones 13½ pounds. In May, 1900, the patient began to have uneasy sensations after food, with rumbling and water-brash, and she discovered a lump in her epigastrium. These symptoms gradually got worse until she was unable to take any solid food. She was readmitted into the infirmary on July 18th. Previously to this she had vomited three times. Her general condition was good. Under the abdominal scar there was a definite hard, nodular, and tender tumour about three inches across and two inches from above downwards. It was adherent to the anterior abdominal wall, but moved slightly with respiration. The stomach was dilated. There were no signs of dissemination. On the 24th her abdomen was opened. The scar was adherent to the stomach; there was a large tumour extending from the pyloric end of the stomach along the lesser curvature nearly to the œsophagus and along the greater curvature to within four inches of it. Near the duodenal end the growth was adherent to the liver, but did not appear to involve the latter. There were several enlarged glands in the lesser omentum. The abdomen was closed, nothing being done. The patient made a good recovery from this exploration. On August 7th her weight was reduced to six stones nine pounds. On Sept. 14th the patient was reported to be worse. She had frequent retching and was unable to take solid food. In October she was getting worse and was only kept comfortable by living upon liquid food and taking sedatives. In December, 1900, three years and two months after the first operation, she died at home. There was no necropsy.

CASE 2.—The patient was a male, aged 48 years. Two months before his admission into the Newcastle Royal Infirmary he felt a burning and discomfort after food, which gradually increased until he could take no solids. He had never vomited. He had become pale and weak, and had lost fully a stone in weight Beneath the upper end of the left rectus abdominis muscle immediately below the costal margin a hard nodulated tumour could be felt, ascending and descending with respiration. On turning the patient on to his right side the tumour moved over for two inches. Pylorectomy was performed on Sept. 12th, 1898.

After the operation the patient rapidly improved and went to work in December. On August 7th, 1899, he reported himself. He looked in good health, and was able to eat and to digest ordinary food. He weighed 10 stones which was his normal weight. He was working regularly from 6 A.M. to 5 P.M. and earning 8*s*. a day. On Sept. 28th he was well; on Feb. 5th, 1900, he complained of not feeling so well as before, and had lost seven pounds since the previous September. There were no stomach symptoms, but there was a small nodule in the skin of the abdominal wall immediately to the right of the scar. There were no other signs of recurrence or dissemination. On August 29th he returned with a large mass in the epigastrium, firmly adherent to the parietes. He complained of pains shooting to the shoulder. There was no vomiting or other stomach symptom. From this time he steadily got worse and died on Nov. 3rd, 1900, two years and two months after the operation. Dr. J. Ingram of Wallsend, under whose care the patient had been, was fortunate and enthusiastic enough to obtain a necropsy. There was no sign of growth in the stomach itself. The suture line formed a firm fibrous ring which just admitted two fingers. The glands surrounding this orifice were enlarged and infiltrated with growth, but they were quite easily separated from the stomach. The liver was studded throughout with large masses of growth.

CASE 3.—The patient was a woman, aged 41 years. Fourteen months previously she had gastric pain, vomiting commenced 10 months before, and latterly she had been unable to retain any solid food. Her stomach was much dilated. In the neighbourhood of the pylorus a hard, freely moveable tumour of the size of a walnut was found. She was very thin, weak, and anæmic, and weighed six stones 11 pounds. Pylorectomy was performed on Sept. 19th, 1898.

After the operation the patient quickly improved, and on March 24th, 1899, she weighed eight stones. She was very well, and able to work and to maintain her family until May, when she began to have stomach symptoms—burning in the epigastrium, with retching and loss of appetite. On July 13th she came to the infirmary. She looked very ill. Her stomach symptoms had increased and there was a large hard mass in the epigastrium which appeared to be a malignant growth. On August 10th she was much worse; the mass was larger and she had severe diarrhœa. She died in December, 1899, one year and three months after the operation. There was no necropsy.

CASE 4.—The patient was a male, aged 38 years. Six weeks before admission he commenced to vomit and had done so every day since. He had become pale and anæmic and had lost 22 pounds in weight A tumour of the size of a cocoanut, moving freely on respiration and on manipulation, was found in his epigastrium. During the few days of his stay in hospital previously to operation it was observed that the tumour was increasing in size. His weight was nine stones 11 pounds. Pylorectomy was performed on Oct. 18th, 1898.

On Sept. 15th, 1899, the patient returned to report himself. He appeared to be in perfect health and was able to take ordinary food, and had gained two stones six pounds in weight. In September, 1900, he wrote to say that he was perfectly well and had gained a further seven pounds. He sent his photograph and this made him look robust. In March, 1901, he was perfectly well and was able to eat anything. At this time he was working as a timekeeper for 12 days out of every fortnight. He had lost four pounds since September, 1900. At the latter end of this month he had a febrile attack, accompanied by much pain in the right side of the chest, said to be due to influenza and pleurisy. Convalescence from this illness was slow and incomplete, and he began to lose ground. By June he had lost another 16 pounds. On July 19th he returned to the infirmary. There were signs of a large local recurrence with deposits in the liver. He had lost other 12 pounds. On August 2nd he was readmitted into the infirmary; he was then extremely jaundiced, thin, and ill. The mass in the epigastrium had increased and the liver was much enlarged. There were a good deal of pain and frequent vomiting. On Sept. 19th, 1901, two years and 11 months after the operation, he died at home. There was no necropsy.

CASE 5.—The patient was a male, aged 41 years. He had been ill and vomited after food for five months; he had also vomited blood. He had lost three stones in weight since the commencement of his illness and was in a very feeble condition. His stomach was much dilated and he vomited sarcinous matter. A small tumour could occasionally be felt in the neighbourhood of the pylorus. He weighed six stones 10 pounds. Pylorectomy was performed on Feb. 9th, 1899.

# SOME FIGURES AS REGARDS SUSCEPTIBILITY TO REVACCINATION.

BY F. W. ANDREWES, M.D. OXON., F.R.C.P. LOND.

WITHIN the past three months it has fallen to my lot to revaccinate a large number of the female staff of St. Bartholomew's Hospital, including sisters, nurses, wardmaids, and servants. In all, I inoculated 171 persons, of whom 163 were vaccinated with lymph from the same source and, I believe, of very uniform potency. I kept a note of the results and have reduced the figures to tabular form. I am induced to record them for several reasons Statistics concerning vaccination deal chiefly with the incidence of small-pox upon vaccinated persons; very few figures are available to show the percentage of persons susceptible to revaccination in young adult life. Although the number of cases here recorded is comparatively small, yet the figures may be of use to someone collecting statistics on a larger scale and their publication may induce others to record their own results. The figures are quite in accordance with what might have been anticipated, but this seems no reason for refraining from publishing them. On the contrary, the lesson they teach is one which at the present moment is most urgently needed to emphasise the importance of revaccination.

The method of vaccination employed was uniform in every case. No antiseptic was employed at all. The arm was scrubbed well with warm water and soap and was then dried with a pad of clean absorbent wool. It was then scarified lightly with a scalpel in four places, each area treated being about one centimetre in diameter. The lymph was immediately expelled from the tube upon the scarified areas, well rubbed in with a sterilised glass rod, and allowed to dry. No secondary infection or other untoward result occurred in any case. The lymph used was that supplied by the Association for the Supply of Pure Vaccine Lymph, 12, Pall Mall East, London, W. It was a glycerinated lymph almost free from extraneous micro-organisms. Before I began to use it I tested a tube by bacteriological culture and found that very few colonies of bacteria grew. The different consignments of this lymph appeared uniformly active.

Of the 171 persons inoculated two were previously unvaccinated, leaving 169 cases of revaccination. Of these I exclude eight cases in which an inert lymph was used inadvertently, thus confining the figures to the cases in which one uniform and good lymph was employed. In three cases I was unable to ascertain the results, owing to the persons who were vaccinated leaving the hospital within a few days after the operation. The following figures relate to the 158 cases in which I can vouch for the results. I classify the results under three headings: (1) perfect vaccinia—i.e., large well-formed vesicles resembling those of primary vaccinia in all respects save that the process was often accelerated by a day or two; (2) imperfect vaccinia—i.e., the production of vesicles small, imperfect, and generally much accelerated; and (3) negative result—i.e., transitory redness without the formation of any vesicles at all.

The gross results of the 158 cases work out as follows: perfect vaccinia, 72 cases, or 45·57 per cent.; imperfect vaccinia, 65 cases, or 41·14 per cent.; and with a negative result, 21 cases, or 13·29 per cent.

If the cases are grouped the results are more striking. 55 of them were wardmaids and domestic servants employed about the hospital—young adults who for the most part had not been vaccinated since infancy. 88 were nurses who are obliged to be revaccinated before entering upon their hospital training. A few had managed to evade this regulation, while in some the revaccination had been unsuccessful, but the great majority of this class were already successfully revaccinated persons, some having been vaccinated several times. 15 of the cases were ward sisters or very senior nurses in whom the effects of the revaccination must to some extent have worn off.

Amongst the 55 cases of the servant class the results were as follows: perfect vaccinia, 42 cases, or 76·36 per cent.; imperfect vaccinia, 11 cases, or 20 per cent.; and with a negative result, 2 cases, or 3·64 per cent. Very different were the results amongst the 88 nurses. They were as follows: perfect vaccinia, 24 cases, or 27·27 per cent.; imperfect vaccinia, 48 cases, or 54·54 per cent.; and with a negative result, 16 cases, or 18·18 per cent. The sisters and senior nurses occupied an intermediate position. They showed: perfect vaccinia, 6 cases, or 40 per cent.; imperfect vaccinia, 6 cases, or 40 per cent.; and with a negative result, 3 cases, or 20 per cent.

The full value of the results is, however, seen when the date of the previous successful vaccination is taken into account. 61 of the cases were persons successfully vaccinated in infancy and not successfully vaccinated since. Of these 61 four were under 20 years of age, seven were aged over 30 years, and 50 were between 20 and 30 years old. The average age of the 61 persons was 23·6 years. The results were as follows: perfect vaccinia, 50 cases, or 81·96 per cent.; fair vesicles, eight cases, or 13·11 per cent.; feeble vesicles, one case, or 1·66 per cent.; and with a negative result, two cases, or 3·32 per cent.

In 41 of the remaining cases I was able to ascertain the date of the last asserted successful revaccination. In one case three years had elapsed and very feeble vesicles resulted. In four cases four years had elapsed; two yielded a negative result and two very feeble vesicles. In 11 cases five years had elapsed; five yielded negative results, four very feeble vesicles, two fair vesicles, but none typical vaccinia. In six cases six years had elapsed; two yielded negative results, one feeble vesicles, and three typical vaccinia. In one case seven years had elapsed; typical vaccinia was produced. In seven cases eight years had elapsed; three yielded negative results, two imperfect vaccinia, and two perfect vaccinia. In three cases nine years had elapsed, all yielded imperfect vaccinia. In four cases 10 years had elapsed, and all yielded imperfect vaccinia, but in two the vesicles were fair. In two cases 12 years had elapsed, both yielded imperfect vaccinia, but one with fair vesicles In one case 16 years and in another 18 years had elapsed; the one yielded fair vesicles and the other perfect vaccinia I may add that except for special reasons, such as known exposure to small-pox infection, I did not attempt to vaccinate any person who had been successfully revaccinated within five years.

As I have said, there is nothing in the above figures that might not confidently have been predicted. We are all aware that the immunity against small-pox which vaccination confers is by no means permanent. It is only the anti-vaccinationists who point with glee to the fact that in a given epidemic more vaccinated than unvaccinated persons are commonly attacked, heedless of the interval which has elapsed since vaccination, and seemingly impervious to the conclusion that this is not an argument against vaccination, but the strongest possible argument for efficient revaccination. It is, of course, an open question how far susceptibility to revaccination implies susceptibility to small-pox. Although it is possible that a person who takes fairly well when revaccinated might yet fail to take small-pox when exposed to infection, or take it very mildly, it is nevertheless true that revaccination is the only practical test at our command for determining susceptibility to small-pox, and that immunity against vaccinia is fair proof of immunity against small-pox One is constantly asked when small-pox is prevalent, "Ought I to be revaccinated?" The only answer is, "Be revaccinated and see. If you do not need it, it will not take, and you will suffer no inconvenience; if you need it, you will be well compensated for your inconvenience."

Of the figures which I have put forward above, those which appear to me to be of most importance are the ones dealing with persons never successfully revaccinated. They indicate that during the third decade of life some 80 per cent. of those vaccinated in infancy are most imperfectly protected against small-pox, and I imagine that it is this class which renders the number of attacks during an epidemic larger in the vaccinated than in the unvaccinated whatever the relative proportion of fatal cases may be. The figures which concern those already successfully revaccinated are of less importance. Individual susceptibility here plays an important part which can only be ascertained by actual position. Take the case of a knee. While the operator is doing his utmost to flex the joint the patient is meanwhile striving his utmost, by travelling on his hands, to get away from him. The operator forcibly flexes a little and is satisfied to come again the next day, to repeat the painful process, and so on *ad odium*.

I feel quite certain that to try to break down recent adhesions of a shoulder- or wrist-joint with the patient sitting or standing is fundamentally wrong; a large amount of pain is caused with comparatively little result, for the reason that the patient is in the best possible position for resisting. Anyone who may try my method on the normal shoulder-, elbow-, and finger-joints will, I think, satisfy himself as to its practical utility and as to the limited capacity for resistance which it allows the patient With regard to the knee-joint, owing to the great power possessed by the muscles to prevent flexion, the advantages of the method when tried on the undamaged joint will not be so manifest. Indeed, in such an attempt upon a boy of the age of 10 years who was prepared for what would happen it would be found that he could successfully resist a very large amount of force. This theoretical objection melts away in actual practice, the stiff knee of an adult after eight weeks of splints giving far less resistance than would that of a normal child. I now propose to describe the method as applied to the joints of the shoulder, the wrist, the finger, and the knee respectively.

*The shoulder-joint (right)*—For these manipulations the surgeon stands behind the patient's head. The patient lies flat on his back on a mattress and the surgeon's left hand being placed flat on the clavicle of the affected shoulder he pins the patient to the mattress or the table, preferably to the latter; the operator's free hand then grasping the elbow raises that joint quickly to a level with the shoulder-joint.

*The wrist-joint.*—The patient's forearm is placed on a table in the supine position. The surgeon's left hand pins down the forearm to the table whilst his right, grasping the patient's hand, quickly flexes it to a right angle.

*The finger-joint.*—This joint is treated in a similar way, the hand being placed on the table with its palmar surface upwards.

*The knee-joint.*—The patient lies *prone* on the bed. The surgeons left hand pins down the thigh, whilst his right, grasping the leg above the ankle, quickly flexes the knee.

The following case will serve as an illustration of the method of procedure.

A youth, aged 18 years, fairly well nourished, who was run over by the wheel of a cart, sustained a simple oblique fracture of the femur just above the condyles. The knee-joint was involved evidently and became greatly swollen, doubtless owing in great part to hæmorrhage. The temperature for the first three weeks ranged from 100° to 101° F. For certain reasons no effort was made to flex the knee until the end of the eighth week; it was then attempted with the patient lying on his back. The flexion caused by the passive movement on the first day was almost *nil* and I anticipated a limited movement only of the joint as a final result, but on the next day it occurred to me to turn him over to the *prone* position and pinning him down I brought his leg up to a right angle with the greatest ease, numerous adhesions evidently giving way in the process

There always must be pain when adhesions are broken down, but I claim for this method that the pain is almost momentary; that a large amount of joint movement is obtained at once by means of far less force than usual; that the resistance of the patient, a hitherto almost unconsidered factor, is reduced to a minimum; and finally, that there is great shortening of the period of passive movements owing to the unusually large amount of mobility caused by the surgeon's initial effort. In the knee case detailed above I had prevented adhesions of the patella by moving it from side to side at each visit and it seemed to me when I flexed the knee that this little point was not unimportant.

Richmond.

---

**Stockport and its Health Department.**—Dr. Meredith Young, medical officer of health of the county borough of Stockport, has been granted a special honorarium of £60 in consideration of the extra work thrown upon him by Parliamentary Bills for the extension of the borough boundaries and the promotion of a large water scheme. The other chief officials and their staffs have been treated in a similar generous manner by the town council.

# Clinical Notes:

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

### SUCCESSFUL REMOVAL FROM AN INFANT OF AN OCCIPITAL MENINGOCELE LARGER THAN THE CHILD'S HEAD.

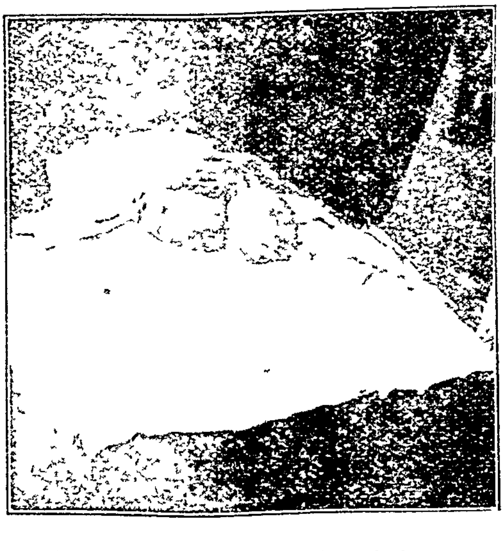
By J. Lynn Thomas, C.B., F.R C.S. Eng.,

SURGEON TO THE CARDIFF INFIRMARY; CONSULTING SURGEON TO THE HAMADRYAD HOSPITAL, TO PORTH HOSPITAL, AND TO CARDIFF PROVIDENT DISPENSARY.

The following case is, I think, worthy of record, as it has to do with one of the largest meningoceles that I have met with—one of the largest, as far as I know, that has been successfully removed. I think that the method adopted in operating upon this particular case is one which diminishes shock considerably, on account of there being no interference with the intracranial pressure during the time of the operation, and also by not having any antiseptics absorbed into the patient's system. There cannot be any doubt, I think, that long preparation of the skin before operation with poisons such as carbolic acid or perchloride of mercury, which are absorbed so easily by the skin, adds very seriously to the shock of a dangerous operation. Dr. W. G. Williams administered the chloroform, whilst my friend and colleague Mr. Cornelius Griffiths assisted me at the operation.

The patient was a male infant, aged four months, and the notes taken of the condition were as follows: "Since birth the child has had a tumour at the back of his head which has been getting gradually larger. It is attached to the skull by a pedicle over the posterior fontanelle, and is of the shape of a very large fœtal head. It is translucent and fluctuating, has been tapped several times, and has a number of large veins visible upon its surface where the skin is thin. The child has never been able from birth to move his head on account of the enormous size of the meningocele. Measurements: diameter of pedicle, three inches; from skull to summit of tumour, five inches; across greatest diameter, seven inches; greatest circumference, 17¾ inches; and occipito-frontal circumference, 15 inches. The tumour is two and three-quarter inches bigger than the largest circumference of the head."

The operation was proceeded with on Sept. 24th, 1901. In order to avoid shock no antiseptics were applied to the field of operation. The necessary preparation of the skin was done immediately before operating. Skin flaps were dissected off the meningocele, leaving the numerous veins untouched. The blood-vessels were under-run and divided between a series of two Kocher forceps and were then reflected back towards the skin. A pair of strong occlusion forceps, six inches long, were then applied to the pedicle and gradually



Shows the meningocele larger than the head.

On March 24th, 1899, he weighed seven stones 10½ pounds. He stated that he felt in good health, and that he could eat ordinary food. Shortly after this he became ill again with pain and vomiting. He gradually got worse and died at home, so far as we could learn, about six months after the operation. There was no necropsy.

Newcastle-on-Tyne.

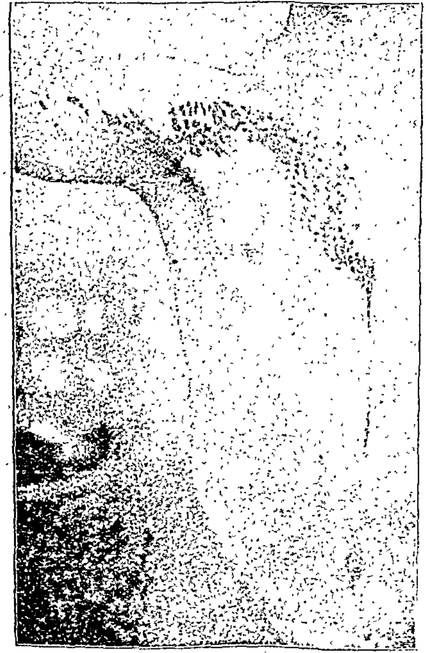
# NÆVUS VERRUCOSUS ASSOCIATED WITH CERTAIN ANOMALIES OF PIGMENT.

*BY H. TAYLOR, M.A. CANTAB., M.A., M.D. DUB.*

THE marked manner in which the lesions are rigorously limited to the right side of the patient, their distribution in the track of certain cutaneous nerves, the alternation of deeply pigmented papillomata with merely the presence of pigment in the skin, and finally the merging of this pigmented condition into decolourised patches, make, I venture to think, this case of nævus verrucosus worth recording.

The patient is a lad, some 19 years of age, well nourished and in good health, with no history of syphilis or tubercle, who displays on his right breast a fairly extensive nævus verrucosus. Over the right pectoral region there is a dense crop of pigmented, non-hairy warts extending into the axilla and, though somewhat thinning out, half-way down the inner aspect of the right arm. At about the level of the nipples the warts reach the median line of the body, but they gradually disappear and are replaced by a line of reddish-brown pigment which is continued down to the umbilicus where again a few growths appear. (See Fig. 1.)

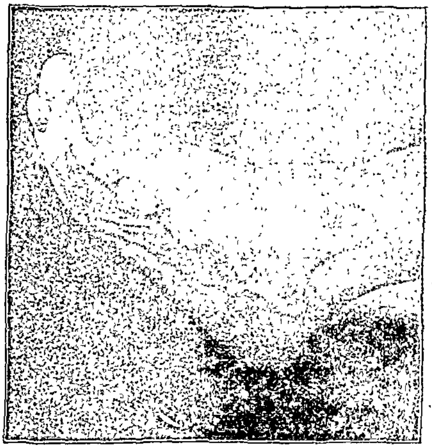
FIG 1.



Crop of pigmented non-hairy warts.

From the umbilicus to the pubes another faint brown line can be traced, unaccompanied by any warts, but on the right side of the scrotum and penis some can be found and with them a few reddish scars, the site of previous ones which the patient states have "dropped off." Similar scars can be seen on the right side of the forehead, nose, and chin, the result of treatment with the actual cautery. Down the inner side of the right leg, from the groin to the inner malleolus, is another faint line of pigment which becomes more marked behind the ankle and is apparently merged into five or six oval-shaped, raised, colourless patches of a leathery consistence, placed along the inner edge of the right foot ("white moles" of Hutchinson?). (See Fig. 2.)

FIG. 2.



Nævus verrucosus associated with certain anomalies of pigment.

There are no skin lesions of any description on the left side of the patient; all are confined absolutely to the right. The patient asserts that he sweats more freely over the affected side and that the principal inconvenience which he labours under arises from this hyperidrosis, with—in a not too cleanly person—the inevitable decomposition of the sweat and the consequent chafing of contiguous parts. The condition is congenital and the various patches have grown only proportionately with the individual. There is no history of any of his relatives having been similarly affected.

The warty growths over the pectoral region are well illustrated in Plate 35 of Mracek's "Hand Atlas of Skin Diseases."

# A NEW METHOD OF BREAKING DOWN RECENT ADHESIONS.

BY GEORGE W. ORD, L.R.C.P. LOND., M.R.C.S. ENG.

To break down adhesions *without an anæsthetic* in either hospital or private practice is, owing to various causes, often a matter of necessity. The passive motion which follows the breaking-down, always a painful proceeding, frequently takes the form of fine-drawn and repeated agony. In private cases the surgeon's individual reputation will suffer if a stiff joint should result, and passive movements, owing to the pain they cause, lead in too many cases to latent resentment, an apprehensive dread of the practitioner's visit, and sometimes to an absolute refusal to undergo the torture. Our policy is, therefore, to be sure and brief in our manipulations and to avoid making passive movement the prolonged tussle between practitioner and patient, or between masseur and patient, which has so far seemed to be inevitable.

The method which I am about to describe consists in fixing the part *above* the stiff joint, by means of the surgeon's left hand, to the bed or the table, as the case may be, and then quickly flexing or causing movement in the joint. Adhesions in the wrists, the shoulders, and the knees we, I contend, break down without first putting the patient into a proper the house. When the husband recovered his intelligence he stated that he had brought some of the powder from the pit and that his wife had used this to sprinkle the floor in order to kill cockroaches. This being mentioned to the wife was denied by her, and she suggested that her husband "must still be wandering." It was not until she was confronted by the police with a tin which still contained traces of powder that she admitted having mixed roburite with some insect destroyer and having sprinkled the beds therewith.

*Remarks by* Dr. R. PROSSER WHITE.—The above forms a typical clinical picture, with the exception of some of the more acute gastro-intestinal symptoms, of the conditions found in persons suffering from the absorption of small doses of dinitro-benzene. Dinitro-benzene is the active ingredient of many of the high explosives, roburite amongst the number. An interesting feature of these cases is the presence of the febrile movement, giving evidence, as it does, of active metabolism caused by ingestion of very small quantities of this poison. This metabolism appears to take place immediately in the blood tissue by the destruction of the blood corpuscles.

The Manchester correspondent of THE LANCET in the issue of Dec. 7th, 1901, p. 1613, unwittingly remarked that the poisonous effects were due to the roburite fumes. As a matter of fact, dinitro-benzene is not in the least volatile at the ordinary temperature of the body; but, on the other hand, this poison penetrates through the skin with remarkable facility.[1] The admixture of even a small quantity of roburite, which contains about 7 per cent. of pure dinitrobenzene, with a practically inert insect-powder such as is commonly used for killing fleas and bugs sprinkled over the bedclothes, and thus coming in contact with the skin, would be amply sufficient to produce the startling symptoms found both in this series of cases and in those occurring at Huyton. In this connexion it is interesting to note that the mother suffered less than the rest of the family. This is explained by the fact that she was out of bed during a considerable part of the night attending to the other members of the family as they were taken ill, thus being for a shorter time exposed to direct contact with the poison.

## PATHOLOGICAL SOCIETY OF LONDON.

*The Experimental Production of the Osteo-arthritic Variety of Rheumatoid Arthritis.—On the Occurrence of Suprarenal "Rest" Tumours in the Pelvis.—Multiple Osteomata.—Specimen of Intestinal Obstruction from Gall-stones.—Congenital Malformation of the Heart.*

A MEETING of this society was held on Jan. 7th, Mr. WATSON CHEYNE, the President, being in the chair.

Dr. F. J. POYNTON and Dr. ALEXANDER PAINE communicated a paper on the results of an Experimental Investigation with a Diplococcus isolated after death from the Knee-joint of a man, aged 67 years, who had suffered from Chronic Arthritis. The cause of death had been carbolic acid taken by misadventure while engaged in his employment. Several joints were found much damaged by the arthritis, and the changes were such as were usually associated with the rheumatoid arthritis of later life. Thus the fluid in the joint was almost clear and was scanty in amount; there was a small foreign body formed probably by the organisation of inflammatory exudation. The cartilages were eroded and the bones were eburnated. The synovial membrane was much thickened. A diplococcus was demonstrated in the unincubated and incubated synovial membrane and was isolated and grown on blood agar. Injected intravenously into two rabbits, arthritis resulted in both instances without either valvulitis or suppuration in the viscera. One rabbit was killed on the fifteenth day. No erosion of cartilage or alteration in the bones forming the joints was found. The other developed a monarthritis of the right knee, with wasting of the muscles of the thigh and leg. The animal was killed in the tenth week and the specimen was shown to the society. The exudation was scanty, clear, and sterile. The cartilages were ulcerated in some places and in others had lost their gloss. The articular surfaces of the bones were slightly flattened, in places ulcerated, and their edges much thickened and lipped. The muscular atrophy was quite definite. The joint capsule and periarticular tissues were but little thickened, but the crucial ligaments were opaque and swollen. A condition of osteo-arthritis had resulted from the intravenous inoculation of a diplococcus isolated from a case of rheumatoid arthritis. Dr. Poynton and Dr. Paine pointed out that other investigators had isolated micro-organisms from the exudations in rheumatoid arthritis; for example, Max Schüller, Bannatyne, Wohlmann and Blaxall, and Chauffard and Raymond had isolated bacilli, and von Dungern and Schneider a minute diplococcus. Dr. Poynton and Dr. Paine emphasised the fact that the monarthritis in their investigation had been the result of an intravenous inoculation and not of a direct injection into the joint and summarised their conclusions as follows: 1. A diplococcus was present in the synovial membrane of the knee-joint of a man, aged 67 years, several of whose joints showed the chronic destructive changes of one type of rheumatoid arthritis. 2. This diplococcus had been isolated and cultivated. 3. Intravenous inoculation into rabbits had upon two occasions produced arthritis without cardiac lesions. 4. The organism had been isolated from the joint exudations. 5. In one instance an osteo-arthritis had resulted which was non-suppurative. This form of arthritis Dr. Poynton and Dr. Paine had not observed hitherto in animals inoculated with the diplococcus of rheumatic fever. 6. They considered this diplococcus to be the cause of the arthritis both in the case from which it was isolated and in the rabbit. Cultures of the diplococcus and sections showing it *in situ* in unincubated and incubated fragments of the synovial membrane were demonstrated. The diplococcus rheumaticus was also demonstrated in the synovial membrane from a case of early rheumatic arthritis. Macroscopic specimens of the arthritic changes were also shown with pipettes containing the fluid removed from the affected parts.—Dr. A. E. GARROD thought that chronic rheumatoid arthritis resulted, not from one cause, but from several different causes, and instanced its occurrence in hæmophilia and in Charcot's disease. He thought that the condition resulted from chronic inflammation of the joint long continued. He doubted if all the cases which were clinically grouped as cases of rheumatoid arthritis could be pathologically proved to be identical.—Dr. J. DRYSDALE asked if the experiment recorded was an isolated one or whether other animals had been inoculated.—Mr. S. G. SHATTOCK thought that a detailed history of the patient's past illnesses was very essential, for he might have suffered from rheumatic fever. He asked whether the articular cartilage showed the fibrillation which was characteristic of a rheumatoid arthritic joint.—Mr. W. G. SPENCER suggested the possibility of a gonorrhœal infection and thought that the organism did not differ very widely from the gonococcus.

Dr. A. EASTWOOD read a paper on the Occurrence in the Pelvis of Malignant Tumours Originating from Suprarenal "Rests." After referring to the frequency of aberrant suprarenal tissue along the course of the spermatic and ovarian veins and in the broad ligament he called attention to a case under Dr. F. H. Champneys' care which he had examined of a large malignant tumour attached to the fundus uteri, but separated from it by a capsule, which he considered to possess the typical feature of a suprarenal malignant growth. He had been unable to find any case previously recorded which could be considered comparable with it both in situation and in microscopic features. He arrived at his diagnosis by first excluding, mainly on histological grounds, other gynæcological possibilities, such as rare forms of sarcoma, endothelioma, the tumours originating from Wolffian remains as described by Recklinghausen, the mixed congenital tumour of Wilms, and then observing that all the features of the present case were not only consistent with, but were highly typical of, a suprarenal tumour. He referred in particular to the capsule, the grouping of the cells suggestive of zona glomerulosa, the close relation of the cells to the blood-vessels, the presence of coagulated material resembling the colloid of the thyroid, and the epithelioid character of the cells which contained yellow oil globules and sometimes pigment. He further supported his view by showing, for comparison, two other cases of Suprarenal "Rest" Tumours Growing in Connexion with the Kidney. He then briefly alluded to the light which suprarenal tumours threw on the question of the internal secretion of closed whilst the meningocele was tapped. The pedicle was rendered watertight by means of a Gely's suture and two rows of continuous sutures. The skin flaps were brought together and collodion dressings were applied. The recovery was uneventful.

[1] Vide Dr. R. P. White and Dr. John Hay: "Some Recent Inquiries and Researches into the Poisonous Properties of Naphthalene and the Aromatic Compounds," THE LANCET, August 31st, 1901, p. 582.

The child at the present time (Nov 6th, 1901) can move his head about, seems to be much more intellectual than he was formerly, has put on flesh, and has greatly improved in general appearance. The bony boundaries of the opening in the occipital region are three and a half inches long by two and a half inches wide.

The illustration is from a photograph which was taken immediately before the operation was commenced, and it shows fairly well the size, shape, and characters of the meningocele.

## AN UNUSUAL COMPLICATION OF INFLUENZA

BY J. G. CARRUTHERS, M.R.C.P. EDIN.

ON Nov. 11th, 1901, a case of typical influenza came under my notice. The subject was a healthy man, 34 years of age, of good physique and good habits. The disease progressed in the usual manner until Dec. 1st, when a quantity of venous blood was passed per rectum, each evacuation consisting of quite a pint. This continued at three-hour intervals for 36 hours, when it ceased. Acetate of lead and opium were administered. The immediate effects of the hæmorrhage were recovered from, but the patient died on Dec. 10th from exhaustion resulting from influenza. At the time of the hæmorrhage the idea of a perchloride injection occurred to me, but in default of localising any lesion it also occurred to me that general peritonitis might be set up by an injection, so I preferred the opium and lead

This is so unusual a complication that I shall be glad to hear of any explanation My own idea is that it was due to a passive congestion of the inferior hæmorrhoidal veins ; why or wherefore ? Someone may explain.

## ROYAL ALBERT EDWARD INFIRMARY, WIGAN.

### REMARKABLE CASES OF ACUTE POISONING BY DINITRO-BENZENE.

(Under the care of Mr. E H. MONKS.)

THE poisonous symptoms of dinitro-benzene are very striking, and owing to the fact that it is at present extensively employed in the manufacture of several explosives it has produced a large number of cases of poisoning. Although at ordinary temperatures dinitro-benzene is not volatile, yet it will readily cause symptoms of poisoning if the temperature is at all raised. Huber[1] quotes a case of a student who prepared some of this substance, and although he was occupied with the work for only one and a half hours, yet his face became deep blue in colour. The urine is black in colour, and it has been shown by MacMunn[2] that this tint was due to a pigment belonging to the aromatic series. There seems to be in some people a well-marked idiosyncrasy to the poison, for all workmen are by no means equally affected. In the following cases of poisoning by this substance it is interesting to note that the person first affected was a small child. This is what might have been expected, as in these cases the poison was absorbed by the skin, and the smaller the body the greater area its skin has in proportion to the body-weight. It is thought[3] that one-tenth of a gramme per kilogramme of body-weight would prove fatal ; if this be so the fatal dose for a human being would be about eight grains. In most cases recovery follows rapidly. For the notes of the cases we are indebted to Dr. H. Holmes, house surgeon.

On Nov. 21st, 1901, the members of a family, consisting of the husband, aged 40 years ; the wife, aged 40 years ; and five children, aged respectively nine, seven, four, two and a half years, and two months, were admitted into the Royal Albert Edward Infirmary, Wigan. They were sent in by the police under the suspicion of having been poisoned. A note accompanied them from Mr. J. E. Parker of Ince who had attended them before admission, in which the following account was given. The man, a collier by occupation, had been out of employment for some time, but had obtained work a few days previously. For the last three days the family had subsisted on only one meal a day ; the last was partaken of at 9 P.M. on the previous evening and consisted of liver, bacon, and potatoes, with tea and bread-and-butter. Mr. Parker said that he was able to exclude ptomaine poisoning, but suspected that some irritant might have been introduced into the food.

On admission the mother was able to give the following account. She was awakened shortly before 3 A.M. by the child, aged four years, complaining of abdominal pain, followed by vomiting and diarrhœa. During the course of the next few hours the others were successively taken ill with headache, malaise, and pain in the stomach. This latter symptom was not observed in three of the cases. At 6 A.M. the father started to go to work, but had to return owing to being giddy and feeling generally ill. They were sent into hospital about 2 P.M. and all were found to be markedly cyanosed, with quickened and shallow respirations and fast and soft pulses The symptoms as observed in the man were as follows. The face, particularly the ears and lips, was almost livid. The skin over the whole body was dusky and the extremities were nearly as dark as the face. His mental condition was peculiar, he being drowsy and lethargic but very irritable when disturbed. He appeared to be unable to comprehend what was said to him His pulse was 120, of full volume but very compressible ; the respirations were 26 The temperature was 99 4° F The pupils were not dilated ; ophthalmoscopic examination showed that the veins were very dark in hue and swollen The urine was of a somewhat high colour and was free from albumin and sugar. The lividity appeared to increase during the first two hours after admission The temperature remained raised during the night, the highest point registered being 100 4°. At 10 A.M. next morning it was normal and was afterwards subnormal till the date of his discharge. During the course of the night the man's mental condition cleared and in the morning he complained of intense headache, "as if his skull would burst," and of pain in the hepatic region. On examination no tenderness or enlargement of the liver was discovered. The lividity was now much less, and in the course of the following day it entirely disappeared. This patient had neither vomiting nor diarrhœa. The other cases all showed symptoms similar to the above, the woman being least affected. In her case intense headache was the only symptom in addition to the cyanosis. In all the cases there was a slight rise of temperature, with pulses ranging from 100 to 140, and accelerated respirations. Two of the children vomited.

The treatment was as follows. The stomach pump was used in the case of the father and the mother. There was but little in the stomach, and the fluid obtained gave no indication of the cause of the trouble. Stimulants, strychnine, and inhalations of oxygen were given. It was noticed that each administration of oxygen relieved the breathing, though it made no appreciable difference in the colour.

All of the dangerous symptoms had passed away before the end of 24 hours, though lividity lasted in most cases two or three days longer, at the end of which time pallor was the only noticeable symptom The patients left the infirmary after six days all apparently in excellent health. From the first it was suspected that the trouble was due to dinitro-benzene or an allied poison, but the mother on being questioned emphatically denied that there had been roburite in removed the kidney. The specimen showed congenital stenosis of the ureter at its origin from the dilated renal pelvis.

---

[2] Brit. Med. Jour., March 3rd, 1894, p. 453.

[3] A. Wynter Blyth Poisons, their Effects and Detection. Third edition, p. 159.

Mr. Roughton also showed a man with Partial Rupture of the Brachial Plexus. An exploratory operation had shown that the seventh and eighth cervical nerves had been torn out of the inter-vertebral foramina.

Mr. Roughton then brought before the society a case of Internal Derangement of the Knee-joint. A loose transverse (inter-semilunar) ligament had been removed by operation with a successful result.

Dr. L. Guthrie showed a man, aged 24 years, who complained of difficulty in walking for 12 years and now exhibited the following symptoms of Friedreich's disease: ataxic reeling gait; unsteadiness on standing, especially with closed eyes; absence of knee-jerks; laboured, slurred, and indistinct speech; nystagmus on external deviation of the eyes; clumsiness and over-action in use of the upper extremities; and antero-posterior kyphosis of the dorsal vertebræ with lumbar lordosis. His discs were normal, his muscular development and power were good, choreic movements and lightning pains were absent, sensation was unaffected, and intelligence was unimpaired. There was no family history of the disease or of any other nervous affection and no parental consanguinity. His personal history was peculiar. In August, 1889, he fell from a bicycle and a few days later from a swinging gate, but appeared to have sustained only trifling injuries. A month later he complained of frontal headache and rapidly lost the use of his arms and legs and his speech, and feeding was difficult on account of spasmodic closure of the jaws. There were also twitchings of the eyelids, the mouth, and the hands, and jerking movements of the whole body and the head, but there was neither loss of consciousness nor sphincter trouble. Mr. W. T. Newton, under whose care he was, thought that the symptoms strongly resembled those of chorea. In November, 1889, he was admitted into St. Bartholomew's Hospital under the care of Sir Dyce Duckworth, when the only symptoms noted were weakness of the legs, spastic gait, loss of the knee-jerks, tenderness of the cervical and dorsal vertebræ, a drawling, monotonous voice, and a faint systolic mitral bruit. His condition had therefore not appreciably changed for 12 ears. The apparent onset of the disease might have been n attack of genuine chorea, but Friedreich's disease was ot uncommonly mistaken for chorea. It was, however, ost unusual for the choreic movements in Friedreich's isease to subside as in the present case.

Mr. Jaffrey showed a woman, aged 58 years, with ultiple Tumours on the Forearm. Several small swellings ere noticed 14 months ago and caused so much pain that he could not do her work as a charwoman. There was no istory of syphilis, but there was a strong family history of hthisis. On the outer side of the upper part of the right forerm were several small, very hard, prominent, subcutaneous umours, variable in size, moveable on the subjacent tissues, nd under the skin. The induration diminished under iodide f potassium. One of the tumours had been removed for icroscopical examination. The diagnosis, he thought, lay etween gummata, fibromata, and sarcomata. Bazin's disease ad been suggested.

The cases were discussed by the President, Dr. Ewart, r. Boyd Joll, Dr. Guthrie, Dr. C. S. Jaffé, Mr. Jaffrey, nd Dr. Cautley.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### Section of Obstetrics.

*Cæsarean Section.—Ovarian Cystomata.*

A meeting of this section was held on Dec. 20th, 1901, r. W. J. Smyly, the President, being in the chair.

Dr. A. Horne read notes on a case of Cæsarean Section nd showed the patient, a married woman, 23 years of age nd four feet four inches in height. She was admitted into he National Maternity Hospital, Dublin, on July 21st, 1901, eing then in labour for the second time. Her first labour ook place in the Rotunda Hospital in October, 1898, and sted some 10 hours, a dead fœtus being extracted after a prolonged instrumental delivery. Dr. Horne found that the distance from the promontory of the sacrum to the lower angle of the symphysis pubis was two and three-quarter inches. The fœtal heart-sounds were audible. Cæsarean section was performed, the operation lasting about 40 minutes; the anæsthetic employed was chloroform at first and ether afterwards. An abdominal incision was made extending from three inches above the umbilicus to two inches above the symphysis pubis. The uterus was delivered through the abdominal wound, which was temporarily united behind it. An incision was made through the uterine wall, commencing high up at the fundus but avoiding the lower uterine segment. The placenta was in front and was rapidly cut through; bleeding was at once profuse. The child was seized by the buttocks and extracted, the head following without any difficulty. The child cried immediately and was found to weigh seven pounds. The assistant's hand grasped the uterine edges until Dr. Horne applied an elastic ligature. The placenta was detached without difficulty. The uterus contracted well, hot sterilised towels being applied; the wounded surfaces were brought together by means of six deep sutures and four superficial silk sutures. The abdomen was closed likewise, using silk for the deep sutures and silkworm gut for the superficial. The progress of the case was most satisfactory. Pain was experienced for only some four hours after operation, and this was relieved by one-sixth of a grain of morphia hypodermically. 30 hours after delivery the patient was given five grains of calomel. She was able to suckle her child. She sat up on the twenty-first day and left the hospital on the thirtieth day after operation.—Dr. J. H. R. Glenn said that he thought that a bold cut going right through the placenta, if it lay in the line of incision, was good surgery. The risk of soiling the peritoneum by the liquor amnii might be avoided by binding round the uterus; bringing out the womb through the abdominal incision added to the shock. For a living child he recommended the Cæsarean section, but if the child was dead he preferred Porro's operation.—The President said that pelvic deformities were not often met with in Ireland compared with other countries. During his seven years' term as master of the Rotunda Hospital he had only four Cæsarean sections and four symphysiotomies, yet from a letter he received from Glasgow he learnt that one of the surgeons of a maternity hospital there had nine Cæsarean sections in nine months

Mr. E. Hastings Tweedy exhibited two Ovarian Cystomata. During the examination of the patient prior to operation he had no difficulty in detecting the presence of the smaller tumour, but he utterly failed to recognise the larger, though it extended to the umbilicus and the patient was deeply anæsthetised. He advised an operation. When the patient was on the operating table and deeply anæsthetised she was again examined, but with no more satisfaction than at first. On opening the abdomen a great gush of ascitic fluid came, and he found a large cyst extending to the umbilicus, and all round a "bread-and-butter" mass, which he looked on as indicative of cancer. The term "bread-and-butter" would be found in American literature. Pulling down the peritoneum, he found cancerous masses connected with the loops of the intestines. The patient made an afebrile and uneventful recovery.

---

Bradford Medico-Chirurgical Society.—A meeting of this society was held on Dec. 17th, 1901, Mr. P. E. Miall being in the chair.—The following cases and specimens were shown. Dr. T. Jason Wood: (1) Specimen of Bony Outgrowth from the Third Cervical Vertebra, with cast; (2) Calculus removed from the Common Bile-duct; and (3) a patient operated on 15 months before for Chronic Empyema by extensive removal of the ribs in whom there was no lateral deformity of the spine.—Dr. O. F. M. Althorp: (1) Uterus removed for Procidentia; (2) Ovarian Abscess; and (3) Two Growths from the Large Intestine.—Mr. J. B Hall: (1) Double Pyosalpinx; (2) Ovarian Tumour; (3) Calculus removed from the Ureter after previous Nephrectomy; and (4) Sections of an Umbilical Polypus.—Mr. W. Horrocks showed a Renal Calculus.—Dr. Wood read notes on Two Cases of Renal Calculus. In Case 1 the patient was a man, 29 years of age, who for four years had suffered from a dull aching pain in the right loin. The pain was aggravated by exertion and there had been a few slight attacks of hæmaturia. There was no renal colic. The patient had been long under medical treatment without relief and had up to the present refused surgical operation. The urine was clear and acid and showed a trace of albumin. On August 28th, 1900, the kidney was exposed by an incision five inches in length below the last rib. The kidney was the normal gland, the diagnosis of endotheliomata, and various theories of new growths. He dismissed Ribbert's theory in detail, pointing out the confusion which arose from a vague use of the term, "tissue tension." Mr J. H. TARGETT said that the structure of the tumour was typical of a growth originating from a suprarenal "rest." He had shown that these "rests" existed in the broad ligament and were to be found in still-born fœtuses, but he did not think that they were of common occurrence.—Mr. SHATTOCK said that he was heartily tired of all theories as to the growth of malignant tumour, and he thought that the "tissue tension" theory had even less value than others. He referred to the experiments of Dr. H. L Lack in which he apparently succeeded in producing new growth on a rabbit after injecting scrapings of the ovary into the peritoneum, but neither Dr. Lack nor he himself had been able to repeat the experiment which he regarded as a peculiar coincidence

Mr. L MCGAVIN read notes of a case of Multiple Cancellous Exostoses associated with Chondro-Sarcoma of the Ribs. He showed the bones of the left knee-joint from a patient who about five years ago developed a small hard mass on the right side of the chest-wall for which his medical attendant sent him to Leicester Infirmary. Here the tumour was explored and was found to consist of cartilage. It was thoroughly removed by scraping, but as the wound refused to heal he was re-admitted on two occasions and the same treatment was adopted. Three months ago the mass returned and was accompanied by a foul discharge The tumour was stated to be a chondroma of the ribs. On admission to Guy's Hospital the patient's knee-joints were seen to be in the pathological condition indicated; and he further had several masses about the lower ends of both tibiæ and fibulæ This condition he stated was present before the age of puberty. After his admission the mass, although again scraped, rapidly increased in size, and he died with all the signs of intra-thoracic growth At the necropsy the surface of the right chest between the second and the fifth ribs was occupied by a mass of solid growth, extending from the middle line in front to the post-axillary fold. In the centre of this was a cavity communicating with the thoracic cavity by an aperture nine cubic centimetres by six; the cavity was lined by irregular bony projections and had plates and spicules of bones projecting into it in all directions. The specimen was of interest, firstly, on account of the number and size of the bony masses, and secondly, on account of the association of chondro-sarcoma with epiphyseal ecchondroses or cancellous osteomata. Bland-Sutton quoted a case from Virchow's *Archiv*, reported by Otto Weber, of "multiple symmetrical exostoses, in which a chondro-sarcoma arose in the right hip bone and attained enormous proportions." In the records of Guy's Hospital for the last 12 years 82 cases of all varieties of osteomata were recorded. Of these, in only one was a chondroma of the ribs associated with osteoma of the long bones, excluding the case in question

Mr. H. L BARNARD showed specimens from three cases of Gall-stone Intestinal Obstruction. The first was a calculus removed from the ileum five feet above the ileo-cæcal valve of a woman, aged 37 years. It was two and a half inches long, one and a quarter inches in diameter, and weighed dry 294 grains. The second was the liver and calculi of a woman, aged 63 years. The former showed a fistula between the gall-bladder and the duodenum. The common bile-duct was not dilated. The gall-bladder was divided into four loculi separated from one another by fibrous septa These contained several calculi. The one which had caused obstruction was seven-eighths of an inch in diameter, one inch long, and weighed dry 103 grains. It was taken from the ileum five feet above the ileo-cæcal valve. The patient was a fat woman in whom obstruction had been present for five days The third was the liver and the gall-stone from a patient, aged 68 years. The stone was impacted 10 feet above the ileo-cæcal valve. The liver showed a fistula between the gall-bladder and duodenum through which the stone had passed. The cystic and common ducts were not dilated.

Dr. O. H. FENNELL showed a Heart with Subvalvular Pulmonary Stenosis which had a walnut-sized diverticulum from the sinus of the right ventricle, situated at the right end of the margo acutus. The muscular wall of the process was thicker than that of the rest of the sinus. The Thebesian valve formed a long, slender, hood-shaped process floating free in the auricular cavity.

# HARVEIAN SOCIETY OF LONDON.

## *Exhibition of Cases and Specimens.*

A MEETING of this society was held on Jan. 2nd, Dr. D. B. LEES, the President, being in the chair.

Mr. A. D. REID showed a girl, aged eight years, with Congenital Shortening of the Right Lower Extremity. She was the third child and the labour was normal and easy. There was no family history of importance and no history of injury. The shortening was noticed soon after birth. The present measurements from the anterior superior iliac spine to the internal malleolus showed one and a half inches shortening of the right side. The shortening was in the thigh. The tip of the great trochanter was on both sides in its normal relation to Nélaton's line. There were no wasting of the limb, no limitation of movement, no disability, and there had never been any pain Some compensatory lateral curvature of the spine had resulted Skiagrams showed that the neck of the right femur was set at a much less obtuse angle to the shaft than on the left side, thus accounting for the shortening

Mr. F. JAFFREY showed a boy, aged seven years, whom he had trephined for doubtful cerebral disease. The boy had been admitted into the Belgrave Hospital for Children on July 29th, 1901, under the care of Dr. Cautley, having been taken ill suddenly three days before with severe headache and screaming. There was a doubtful history of a blow on the head The weather was very hot but nothing in the history definitely suggested heat-stroke. On admission the boy was drowsy, irritable, and stupid, and he took little interest in anything The head was a little retracted and the knee-jerks were exaggerated. There was no optic neuritis or evidence of ear disease. On August 1st he developed severe convulsions which were most marked in the arm, the leg, and the face on the right side. The eyes were staring and consciousness was abolished. On the following morning Mr. Jaffrey trephined the skull over the middle of the Rolandic area. On dividing the dura mater it was seen that pulsation was absent and a considerable quantity of cerebro-spinal fluid escaped A grooved director was passed under the dura mater in all directions, and while the fluid was escaping the brain began to pulsate again He did not explore the brain A drainage tube was inserted and kept in for three days The fits ceased, but the boy made little progress for a fortnight, after which he improved so rapidly that at the beginning of September he was on the point of leaving the hospital when he had another attack of convulsions and again became unconscious He remained in this condition for three or four days and then recovered. Since then he had had no further attack, but the parents said that his memory was bad, and until this week he did not voluntarily use his right arm but always used his left.—Dr. CAUTLEY stated that the diagnosis was extremely indefinite and that on admission the boy seemed intensely stupid rather than really ill. The headache was not localised and there were no definite signs of cerebral abscess, tumour, meningitis, or heat-stroke When the fits developed he had suggested operation with a view to relieve pressure. The localisation of the fits more on the right side decided the site for operation, and he had suggested at the time that the case might possibly be due to a latent abscess. There appeared to be little doubt that the operation was of very great benefit and probably of vital importance. He could not suggest what was the exact nature of the cerebral mischief, and the recurrence of the attack a month later, with subsequent immunity, made the case still more puzzling.—Dr. W EWART thought that the causation of the symptoms by excessive intracranial pressure had been demonstrated by the operation itself and by the relief which followed The fact that on their second occurrence the same symptoms, presumably due to the same cause, disappeared spontaneously suggested the view that transient effusions might be thrown out within the meninges and soon re-absorbed again, as this had been shown to occur in the pericardium, the pleura, and the peritoneum. Alarming but not necessarily fatal symptoms might thus be set up in susceptible subjects, but some of the worst forms of effusion and that formerly known as "serous apoplexy" might not be recovered from without surgical relief.

Mr. E. W. ROUGHTON showed a boy, aged five years, who Ruptured a Congenital Hydronephrosis by a fall. He

Lawrence showed a case of Tuberculous Rhinitis in a man, aged 35 years, treated by exposure to the Roentgen rays. The case had made considerable improvement but was not yet cured.—Dr. G. C. Cathcart showed a case of complete loss of the internal framework of the nose in a woman, aged 22 years, and inquired whether it was a suitable case for the subcutaneous injection of paraffin with the object of improving the shape of the nose.—Dr. Scanes Spicer thought that it was a suitable case and he described the technique which he had employed in a case under his own care.—Mr. E. Waggett brought forward a case of Epithelioma of the Epiglottis in a middle-aged man involving the Cervical Glands. Operative measures were thought inadvisable.—Mr. C. A. Parker showed a case of Stenosis of the Pharynx in a woman, aged 37 years, which was said to be connected with an abscess in the neck which she had when she was 10 years old. The epiglottis was bound down to the posterior wall of the pharynx, leaving an opening not bigger than a threepenny-piece.—Cases were also shown by Mr. P. R. W. de Santi, Dr. W. H. Kelson, Dr. V. H. Wyatt Wingrave, Dr. StClair Thomson, Mr. E. W. Roughton, and Dr. H. Lambert Lack.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The fourth meeting of the present session of this society was held on Jan. 3rd, Mr. Alfred Cooper, the President, being in the chair.—The adjourned discussion on Mr. T. R. Atkinson's paper on the Small-pox Epidemic was opened by Dr. Leonard Dobson with a paper on Glycerinated Calf-lymph.—A discussion followed.—Dr. Eddowes drew attention to the importance of the care of the vaccinated arm and Dr. S. D. Clippingdale commented on the especial necessity of tests on the part of those practising among the poor, including public vaccinators.—Dr. Reece spoke on the Government requirements in public vaccination with regard to the area of vaccination, the inspection and treatment of the arm after vaccination, and the inquiry into deaths following vaccination.—Mr. Garry Simpson related his experiences with regard to revaccination, and drew attention to the necessity of extreme care in the details of the act of vaccination itself as well as in the after-care of the arm.—Dr. Bevan spoke on the importance of using an active and trustworthy lymph.—Dr. Chambers pointed out that the degree of protection conferred by vaccination depended to a great extent upon the number of insertions and that the term "vaccination" without a statement as to the number of insertions was vague and rendered statistics illusionary.—Dr. Buttar spoke on the difficulty in defining what constituted efficient revaccination.—At the close of the meeting a proposal was carried with reference to the advisability of the exercise of Government control over the manufacture and sale of vaccine lymph.

CLINICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on Dec. 17th, 1901, Dr. Herbert Lund being in the chair, in the new department of the Manchester and Salford Hospital for Skin Diseases which was opened last spring for treatment by the use of the Finsen Light apparatus and the Roentgen rays.—Dr. H. A. G. Brooke explained the theory and methods of the two treatments, and afterwards showed the Finsen and Lortet lamps and the Roentgen ray installations at work. All were in constant employment and 20 patients were thus treated each hour. A large number of patients were present to show the progress of the treatment in the different stages. The Finsen light and x rays both gave excellent results in lupus vulgaris and in lupus erythematosus, especially on limited foci. He was not satisfied that the Lortet lamp, though of great service and much more rapid, was as thorough in its action as was the Finsen instrument. The x rays had been used with very good effect also in rodent ulcer, varicose ulcers, old sycosis, and acne indurata with from 10-inch to 12-inch tubes at a minimum distance of eight inches from the patient and with sittings every second day. There had been no dermatitis. The rays had also acted beneficially in the treatment of lupus of the palate, gums, and interior nares. A demonstration was also given of the D'Arsonval-Oudin high frequency currents.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—The annual meeting of this society was held on Dec. 2nd, 1901. The office-bearers for the ensuing year were duly elected. Mr. A. H. Cheatle was appointed editor of the society's Transactions.—Mr. R. Lake showed a patient from whom he removed the Necrosed Labyrinth and had secured a very beautiful specimen of the Membranous Cochlea.—Dr. Milligan showed a patient upon whom the complete Mastoid Operation had been performed with Grafting of the Antro-tympanic Cavity. The result was good and the hearing power of the patient had materially improved.—Dr. J. Dundas Grant and Mr. C. A. Ballance showed a patient who had been operated upon for Temporo-sphenoidal Abscess with complete recovery.—Patients and specimens were also shown by Dr. Herbert Tilley, Mr. F. C. Abbott, Mr. Cheatle, Dr. A. Bronner, Dr. Urban Pritchard, and Mr. C. H. Fagge.

# Reviews and Notices of Books.

*Water and Water-supplies.* By JOHN C. THRESH, D.Sc. Lond., M.D. Vict., D.P.H. Cantab.; Honorary Diplomate in Public Health, Royal College of Physicians and Surgeons, Ireland; Medical Officer of Health of the Essex County Council; Lecturer on Public Health, London Hospital Medical College; Fellow of the Institute of Chemistry; Member of the Society of Public Analysts; Associate Member of the British Association of Waterworks; Engineer Examiner in Hygiene, London University, &c. Third edition, revised and enlarged. London: Rebman, Limited. 1901. Pp. 527. Price 7*s.* 6*d.*

DR. THRESH is well known as an authority on all matters pertaining to water-supply, and attention was recently called to the useful handbook which he lately issued on the supply of the county of Essex, of which he is medical officer of health. The excellent little book now before us is of general interest, and this, the third edition, contains additional information on the important subject of the protection of water-supplies.

It may be well to give an outline of the contents of the book. The first seven chapters are devoted to a consideration of the composition and properties of water as found in nature—that is to say, outside the chemical laboratory. The characteristics of rain, surface, subsoil, and deep-well and river waters are separately considered and a chapter is devoted to a description of natural or "mineral" springs, as they are usually called. This part of the subject is briefly treated, but the information given is ample for the purpose of the book which is chiefly designed to give the information requisite for forming an opinion as to whether any proposed source of supply can be justly considered sufficiently good in quality and abundant in quantity for the purpose for which it is wanted, and, further, to give the information necessary to form a judgment as to what the approximate cost should be of using such a supply.

A chapter is devoted to the quality of drinking water, and this is followed by one on impure water and its effect upon health. It is not quite easy to see the reason for the arrangement of the next few chapters. A chapter on the Pollution of Drinking Water is preceded by one on the Interpretation of Water Analysis and followed by one on the Self-purification of Rivers. The subjects next considered are the methods of purification of water on a large scale, domestic purification, the means adopted for softening hard water, the quantity of water required for domestic and other purposes, and the precautions to be used in the selection of sources of water-supply and the method of determining, or at any rate of estimating (which admittedly is not always the same thing), the amount available from a given source.

The protection of underground water-supplies and of surface water-supplies is dealt with in two new chapters which follow. The information brought together in this place deserves the most careful consideration by all those who are in any way responsible for the quality of public or private water-supplies. Had the book been entirely re-written by Dr. Thresh no doubt much of the matter contained in these chapters would have naturally appeared in brought up into the wound and incised on its convex border. A stone which had been felt before incision was removed. No further stone was found. The kidney wound was closed by catgut sutures through the kidney substance and the organ was replaced. A drainage-tube was inserted at the posterior extremity of the wound. The patient made a good recovery and there was no discharge of urine from the wound. In Case 2 a man, aged 30 years, had complained of pain in the right side of the abdomen for about four years. The pain was usually felt at a spot on the linea semilunaris, half an inch above the level of the umbilicus; it sometimes passed through to a corresponding spot on the back, and again was felt at times over the middle of the right iliac crest. The pain came on suddenly without any apparent cause and was not influenced by position, pressure, or movement; the patient said that it was just as likely to come on in bed as at any other time. No other symptoms were present; there were no shooting pains, no pain or frequency of micturition, and no colic, vomiting, diarrhœa, or jaundice. Examination showed the patient to be a fairly healthy-looking man who presented no physical signs of disease. The urine was acid, its specific gravity was 1014, and it contained a trace of albumin, but no blood or sugar. The deposit contained crystals of oxalate of lime and one or two doubtful casts. The total daily quantity was rather less than normal, being 38 ounces. Under ether the kidney was exposed and opened as in Case 1 and five oxalate of lime calculi weighing 60 grains were removed; a bougie was passed down the ureter which was found to be free. The kidney was then irrigated with hot water, closed with catgut sutures, and replaced. In this case the kidney was unusually high up and there was very little loin space, so before the organ could be drawn up into the wound it was found necessary to divide the last rib and to turn it up. The patient made a rapid recovery which was slightly delayed by an attack of acute dermatitis caused by the mercurial dressings. No inconvenience was caused by the divided rib which appeared to have united by the time he left the hospital. Dr. Wood remarked that Case 1 was a pretty straightforward one of renal calculus and the diagnosis presented no great difficulties. Case 2 was different and on the symptoms alone (the pain) the trouble might have been referable to the gall-bladder or to the appendix. The albuminuria and the nature of the deposit directed attention to the kidney as the affected organ. It was rather remarkable that the stones, which were very rough on the surface, should not have caused hæmaturia.—Dr. William Mitchell read notes on a case of Spontaneous Gangrene of Both Lower Extremities in a man, aged 36 years. A vague history of acquired syphilis was obtained from the patient and evidence of it was seen in his wife in the shape of a ham-coloured macular eruption on the face, arms, and chest during the puerperal period. The infant had "snuffles." The patient had been addicted to taking frequent alcoholic "pick-me-ups" during the day for a number of years, but had never been given to inebriety. During the last two years he had had a number of vague illnesses which had been diagnosed as influenza and on one of these occasions he had a slight attack of pleurisy with a persistent elevation of temperature of half a degree lasting for several weeks. The circulatory system, the kidneys, and the digestive organs appeared to be normal. There was present fine tremor of the hands and the tongue; otherwise the nervous system showed no sign of disease. The present illness commenced on Jan. 17th, 1901, with severe pain in the ball of the little toe on the left side, extending along the sole of the foot and a short distance up the back of the leg. The knee-jerks were normal and there was no excessive tenderness on deep pressure over the calf muscles. Tactile sensation was diminished over the little toe only. Pressure over the sole of the foot caused severe pain A diagnosis was made of rheumatism affecting the ligamentous structures of the foot, but no improvement resulted from appropriate treatment. He was sent to a watering place and was under the care of two medical men there who treated him with local hot-air baths and allowed a generous supply of alcohol. The baths caused excruciating pain in the limb, the muscles of which wasted very much, and the patient became very weak and ill. He was then seen by a consulting physician and by Dr. Mitchell, and a diagnosis of peripheral neuritis was arrived at. All alcohol and tobacco were cut off, but the patient still got worse and about the middle of May gangrene of the left foot had set in. As no pulse could be detected lower than the common femoral, amputation was performed seven inches above the centre of the knee-joint by the modified circular method. Nearly all the vessels cut through were thrombosed and there was very little bleeding. Shock was slight Before the operation the pulse was 120 and the temperature ranged between 102° and 104° F. In three days the pulse had fallen to 75 and the temperature to 97 4°. On the fifth day after the amputation gangrene became evident in the right foot, in which there had been vague pains for two or three days. No pulse could be felt in the popliteal space. Amputation was performed the same day six inches above the knee-joint. The shock was much greater than on the first occasion. The vessels were thrombosed and little blood was lost In five weeks both stumps were healed and the patient was able to sit up in a chair. In 10 weeks he went to the seaside and gained two stones in weight in nine weeks, and on his return he felt better and slept and ate better than he had done for years. Since a week after the second operation he had taken no alcohol and had given up the use of tobacco. Before the gangrene set in no symptoms of arterial disease were recognised as such by any of the medical men who saw him On examination of the amputated limbs, however, marked atheroma of the intima of all the main arteries was found in association with extensive calcareous degeneration of the media. These conditions were demonstrated by microscopic sections and by micro-photographs —Dr. J H. Bell gave a short account of a famous Bradford surgeon, William Garnett, to whom Mr. (afterwards Sir) Humphry Davy was at one time assistant.

SOCIETY OF ANÆSTHETISTS.—A meeting of this society was held on Dec. 6th, 1901, Mr. Walter Tyrrell, the President, being in the chair.—Mr. H. C. Crouch read a paper by himself and Mr. E. M. Corner, entitled "Is Chloroform more Dangerous than Ether? Consideration of Respiratory Troubles following Operations during 12 Months at a Large General Hospital" On account of the divergent views held by anæsthetists with regard to respiratory complications after ether inhalation Mr. Crouch and Mr. Corner examined every patient who had an anæsthetic in St. Thomas's Hospital during a certain period, in order to see (1) if ether was responsible for lung troubles at all, and (2), if it was, how it compared with chloroform. They included in their lists only patients in whom chest symptoms accompanied by fever arose within 24 hours. In all just over 3000 patients were examined; 2400 of these had ether, and 600 had chloroform. None of the latter, though they included many mouth cases, had any lung trouble, though 10 of the former had, and one of these died On analysing these 10 cases it was found that they occurred at all ages in persons the state of whose lungs was distinctly good, whereas there was no case in a patient with a previous history of winter cough The patients were all apparently in good general condition and gave no trouble to the anæsthetist; they did not become cyanosed, they did not secrete an excessive amount of mucus, neither did they require an unusual amount of ether; they were all trunk cases except one case of extensive varicose veins, and the operation in every case lasted a long time. Seven out of the 10 occurred in the summer; the respiratory complication was usually bronchitis, but in three of the cases it was broncho-pneumonia. They considered that this after-effect was due primarily to the ether and secondarily to the exposure and tight bandaging after the operation. It was also a question whether the previous administration of an unduly large amount of nitrous oxide had not had some share in it. They recommended that chloroform should be given in all cases where the operation either involved tight bandaging of the trunk or was prolonged When ether was given a loosely folded towel should be placed over the patient's mouth and nose until after removal to a ward with an equable temperature —A discussion followed, in which Mr. Alban Doran, Mr. Carter Braine, Dr. Bromfield, Dr. R. J. Probyn-Williams, Dr Dudley Buxton, and others took part

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on Dec. 6th, 1901, Mr. E. Cresswell Baber, the President, being in the chair.—Dr. E Furniss Potter showed a case of Perforation of the Left Faucial Pillar due to some ulcerative process and not congenital —Dr. W. Jobson Horne exhibited some specimens of Ulceration of the Larynx in cases of Hodgkin's and allied diseases and raised the question whether the local ulcer was the site of entrance of the infecting agent.—Mr. L. A.

phenomena suggested by the author, prove how rapidly and effectively a thorough examination may be completed if carried out according to a well-thought out and systematic method. The whole section on the Examination of the Nervous System occupies 70 pages and concludes with a summary of the various diagnostic points which bear upon the nature and location of cerebral and spinal lesions.

Turning now to Part II., under Diagnosis, Direct and Differential, of Diseases of the Nervous System, we find 60 pages devoted to the subject which is dealt with according to the following classification: Neuroses—(1) sensory, (2) motor, and (3) trophic; Diseases of the Peripheral Nervous System—(1) motor, and (2) sensory; Diseases of the Spinal Cord and Bulb; Systemic Cord Diseases; Inflammation of the Spinal Meninges; and Diseases of the Cerebral Substance. The illustrations in Part II. are necessarily fewer than in Part I., but in special cases where diagrams or illustrations can help the imagination they are supplied with excellent effect According to the above classification associated diseases are grouped together with their points of difference or similarity carefully emphasised. Having made a rough diagnosis by reference to Part I., the diagnosis is completed and substantiated by the confirmatory evidence supplied in Part II., which indicates under the heading of the disease all the important symptoms and diagnostic features.

We believe that we have now given a sufficiently full description of the method of writing and of the method of using this book. In a review of this kind it is impossible, however, to convey an adequate idea of the artistic merits and the scientific ingenuity of the diagrams and illustrations, or, indeed, of the effective manner in which so dry a subject as differential diagnosis is handled and simplified. The least satisfactory portions of the book are those which Dr. Butler did not undertake himself, and this criticism especially applies to the diagnosis of constitutional disease in Part II. The account of chronic rheumatism, diabetes, and gout is altogether inadequate, and the remarks on the subject of heat dissipation in pneumonia in the case of obese subjects are absolute nonsense. With these reservations, however, we may express the opinion that Dr. Butler's work on diagnosis is undoubtedly the best work of its kind.

---

*Handbuch der Physikalischen Therapie (Text-book of Physical Therapeutics.)* Edited by Dr. A. GOLDSCHEIDER and Dr. PAUL JACOB. Part I. Vol. I. Leipsic: Georg *Thieme. 1901. Pp. 578.* With 62 Illustrations. Price 15 marks.

THIS publication is intended to present to the medical profession a complete and detailed account of the various methods of treatment included under the term "physical therapeutics." The modern plan has been adopted of securing a number of contributors who severally have had the opportunities of devoting special study to particular methods of treatment and of embracing all the communications in one publication under the supervision of competent editors. The various measures now adopted for the treatment of disease otherwise than by drugs, or to assist the action of such, have considerably increased during recent years. Much yet remains to be done, however, to establish these therapeutic methods on a true scientific basis, and consequently the appearance of such a work as the one now under consideration is of considerable value as representing fully the present knowledge on the subject.

The first subject considered is that of climate from a therapeutical point of view. The theory of the effects of climate on the human body is well sketched by Professor Rubner of Berlin, whilst the application of the principles to clinical work is given by Professor Nothnagel of Vienna. The two sections are well written and contain a vast amount of information.

The second chapter deals with High Altitudes, the theoretical, or "physiological," part being written by Dr. A. Loewy of Berlin and the clinical portion by Professor H. Eichhorst of Zürich. The latter describes the various high altitude resorts under three headings—namely, those in Germany, Austria, and Switzerland respectively, the last-named naturally receiving the largest amount of attention. Brief attention is also given to the high lands of other countries, such as America and South Africa.

A historical sketch is next given by Dr. Pagel of Berlin of the Therapeutics of Pneumatics and Inhalations. "Pneumatotherapy" is considered by Dr. R. du Bois-Reymond of Berlin and Dr. G. v. Liebig of Bad Reichenhall, the former giving a most valuable account of the physiological effects of rarefied and compressed air, whilst the latter describes the various forms of apparatus which have been devised for the application of such measures for the treatment of disease. The compressed air cabinet receives due consideration. In this country this contrivance has scarcely received the attention which it deserves. Frequent immersion in compressed air has proved most beneficial in the treatment of asthma. Inhalations of various medicaments are largely adopted in the treatment of affections of the throat and chest, and a good account is given by Dr. Julius Lazarus of Berlin of the principal forms now in use.

The fifth chapter is devoted to Balneology, the theoretical considerations being in the hands of Dr. Pagel of Berlin, while the practical application of baths is treated by Dr. J. Glax of Abbazia. The various forms of baths are described and numerous illustrations aid in the description. The remarks on the indications and contra-indications for the use of the baths are, however, scarcely up to the general standard of the work.

The sixth chapter is headed by a word which has not been extensively used in this country—namely, "Thalassotherapie." The meaning is sufficiently obvious, and its application is practically confined to a consideration of the therapeutical value of sea-air, sea-baths, and the benefits or otherwise which may be obtained by sea-voyages. Dr. A. Hiller of Berlin writes on the climatic conditions and on sanatoriums by the sea, whilst Sir Hermann Weber contributes valuable remarks on the clinical use of sea-baths and also of sea-voyages.

The subject of Hydro-therapy is dealt with by Professor Winternitz and Dr. Strasser, both of Vienna. The former is responsible for a long and instructive disquisition on the theory of hydro-therapeutics—the effects of the application of water at different temperatures and by different methods on the innervation of the body, on the muscles, on the circulation, and more particularly on the excretory organs. He points out that the chief effects produced do not depend upon the direct action of the methods employed, but upon the resistance of the organism to the mechanical effects—that is to say, to the reaction that ensues, and it is on the extent of this reaction that the beneficial results of this method of treatment depend.

The last chapter in this part is on Thermo-therapy. A "Historical Introduction" is by Dr. Julian Marcuse of Mannheim, the section on the theory of the subject being by Dr. A. Goldscheider of Berlin.

The publication promises to be an interesting one and we can recommend a study of the part now published to all those who are interested in the special branches of therapeutics with which it is concerned.

---

*Mexico as I Saw It.* By MRS. ALEC TWEEDIE. With numerous Illustrations from Photographs by the Author. London: Hurst and Blackett. 1901. 8vo. Pp. 472.

MRS. TWEEDIE is an agreeable and lively guide. Many readers have enjoyed her society through Norway and through Finland, and they will find undiminished pleasure other parts of the work and it is probable that the force of the teaching conveyed by the scattered facts would thus in some measure have been lost. As it stands the information given is clear, the arrangement is consecutive, and the conclusions are beyond cavil. The following chapters deal with Wells and their Construction, Pumps and Pumping Machinery, and the Storage and Distribution of Water. Mr. John C. Freeman, clerk to the Maldon Rural District Council, is responsible for the revision of a chapter on that rather complicated subject, the Law Relating to Water-supplies. There is an excellent chapter on Rural and Village Supplies. This will be found of very great use to the members of county and rural district councils who in the future will undoubtedly have in this matter great power for good or for evil. Dr. Thresh has had unusual experience in the matter of rural water-supplies, and this book, unlike many more pretentious and less useful ones, deals not only with steam-pumps, but gives information as to oil engines which have been found in certain circumstances to be of great service. The concluding chapter is devoted to the question of water charges. There is a good general index and an index of proper names.

From what has been said it will be evident that Dr. Thresh's book treats of all the most important problems connected with water-supply. It is written clearly and in a way to be of practical use; it is not overladen with pages of useless statistics, and in most cases the results of the inquiries undertaken by other workers in the same field have been assimilated by the author and are reproduced by him with all due acknowledgment and in his own words. In this book slabs of other men's work are not hurled at the reader's head.

As an introduction to the study of the question of water-supply we know of no better book, but it is something more than an elementary work. A great many useful hints will be found scattered through the book. For example, on p. 26 the use of a rain-water separator is recommended; such an instrument proves a great boon in a country house. On the matter of wells in the chalk Dr. Thresh would perhaps have done a better service to his readers had he stated fully the known facts and left the theories to shift for themselves. A good deal of interesting information which will be new to many people is given on waters which possess peculiar odours. The subject has received much attention in the United States of America and Mr. G. W. Calkins has not only made a special study of the offensive odours found in water but has elaborated a scientific classification of them in a manner which would probably have given great satisfaction to the late Dr. J. Swift.

---

*The Diagnostics of Internal Medicine.* By GLENTWORTH REEVE BUTLER, A.M., M.D. With Five Coloured Plates and 246 Illustrations. London: Henry Kimpton. 1901. Pp. 1059. Price 25*s.* net.

NUMEROUS as have been the attempts, both in this country and abroad, to compile a satisfactory work on medical diagnosis, all these attempts have, so far as we are aware, heretofore ended more or less in failure. The reason for this is not far to seek. On the conventional lines of medical authorship it is almost impossible to reconcile the necessities of systemisation with a literary style which can give any pleasure to the reader, consequently works on general medical diagnosis have either been presented in a form which is unwieldy and unpractical from a clinical point of view or excessively dull reading for the student who reads for the sake of learning. "The Diagnostics of Internal Medicine," like many other American works on medicine, is as original in method as it is successful in its execution. On the one hand, it is thoroughly practical and systematic in the arrangement, while on the other it avoids the reproach of dulness by the brightness of the style, the use of leaded and varied type, and by the remarkable excellence of the illustrations which even for an American work are extraordinarily numerous. Dr. Butler has defied the traditional and conservative routine of medical writing with which we are so familiar in this country and has embarked upon a new style of representing disease which cannot help appealing to his readers, whether they be young and inexperienced students or clinicians of experience and years. In character this book is essentially practical in form, and for the sake of variety and convenience it is divided into two parts which deal practically in the same order, but from different points of view, with the same medical subjects. The first part is concerned with the evidences of disease and the second part with the diagnosis, direct and differential—that is to say, the diagnosis of disease is approached in the first part from the point of view of the symptoms and in the second part it is treated as an entity. Part I. is subdivided into 44 sections or natural orders of symptoms, those, for instance, which are referable to diseases of the circulatory organs, of the lungs, of the digestive system, and so on. If we meet with, for instance, a symptom clearly due to abdominal disorder, we turn to the section which deals with the examination of the abdomen, and by a rapid perusal of the same we proceed to one of the following sections which treat of the digestive system, the urinary system, and the other abdominal organs. The systematic mental exercise thus inculcated is indubitably a very excellent training, and further than this it clearly can be applied to the purposes of establishing a diagnosis in actual practice.

In Part I., having discovered the presumable organ affected and the supposed nature of the lesion, we turn to Part II. for, as they are called in analytical chemistry, confirmatory tests. Here under the name of the disease are given the various signs and symptoms whereby the diagnosis can be confirmed. By means of this double-barreled reference the intense monotony of ordinary systematic works on diagnosis is avoided, and the student is trained to refer the symptom to the disease and to picture each disease-entity as a complex of many symptoms.

Having given a general description of the arrangement of Dr. Butler's "Diagnostics" by way of illustrating the ingenious method whereby the reader is assisted to form a diagnosis we propose to describe in greater detail a typical section in the first part and the complementary section in Part II. Selecting at random Section 37, which is concerned with the examination of the nervous system, we find a clear and concise account of the anatomy of the central and peripheral portions, with an excellent diagrammatic representation of the neuron. The motor and sensory paths in the brain, the spinal cord, and the peripheral nerves are illustrated beautifully with coloured diagrams, by means of which the difficulties of understanding this essential and complicated anatomical basis of neurology are reduced to a minimum. To give an idea of the liberality with which the illustrations are supplied we may mention that in the 26 pages devoted to anatomy there are no less than 20 illustrations, many of which are coloured and occupy an entire page. Most of them are original, though a few, such as those of Dr. Head, are copied from other works. Passing from the anatomy we come to the actual examination, which in the case of the nervous system entails consideration of temperament, diathesis, and degeneracy, and the testing of the motor and sensory functions, and includes the subjects of reflexes and muscular mobility. These points, according to their importance, are dismissed cursorily or described in detail. Wherever possible some diagrammatic scheme simplifies the understanding or assists the memory. The method of testing the muscles with reference to their nutrition, tone, and motor-power, as also the investigation of sensory the physico-chemical examination of the blood and of the various secretions and excretions of the body. The final chapter discusses in a brief but clear manner the subject of tissue metamorphosis.

---

## JOURNALS AND MAGAZINES.

*The Practitioner.*—The December issue continues a discussion of Bright's Disease by various writers. A very valuable article on the treatment of the disease is contributed by Dr. W. Hale White who for purposes of treatment divides patients into those suffering from acute Bright's disease and from chronic tubal and chronic interstitial nephritis. While admitting the beneficial action of water in washing out the tubules of the kidney Dr. Hale White points out the danger of permitting too large an intake of liquid. He quotes Edsall in support of the contention that serious nitrogenous loss is entailed by a too free use of water. As much as a quarter of a pound weekly may be lost in weight in this way. Dr. Hale White has no particularly novel method or remedy to advance, but the details of treatment are carefully set out and their *rationale* is explained Egypt is the place most warmly recommended for sufferers from Bright's disease. Another valuable contribution also dealing with treatment is that of Dr. J. M. Groedel. The treatment of chronic nephritis by mineral drinking-waters and mineral baths is carefully considered and the classes of cases suited or unsuited to the Nauheim baths are differentiated. Cases of chronic parenchymatous disease are considered unsuitable, while interstitial cases in which there is as yet no great circulatory disturbance are found to benefit by the treatment. As to the ingestion of the waters, the author is guided chiefly in the amount which he permits by the condition of the pulse. In all cases he has the quantities taken and the quantity of urine passed during the treatment carefully measured daily. The treatment appears to be recommended more for its beneficial effect on the heart's action and the patient's subjective condition than for any direct influence on the renal state. Dr. F E Batten writes on Affections of the Nervous System in connexion with Bright's Disease and Dr. Henry Ashby writes on Nephritis in Children. The editor in another part of the magazine is mainly concerned with the election to the General Medical Council.

*The Journal of Obstetrics and Gynæcology of the British Empire.* Vol. I., No. 1. January, 1902 London: Baillière, Tindall, and Cox. Price 2*s* 6*d* net —With the new year the first number of this journal makes its appearance. The editors announce their intention to make the publication a complete and impartial record of British work, an exponent of British obstetrical and gynæcological practice, and a summary of contemporary thought and achievement in obstetrics and gynæcology throughout the world With the coöperation of the large number of distinguished collaborators drawn from all parts of the empire who have promised their assistance the journal should have no difficulty in fulfilling the purpose with which it appears, and it has our most hearty wishes for its success and prosperity in the future. The first article is one by Dr. C. J. Cullingworth and is entitled "An Analysis of 100 cases of Uterine Fibro-myoma," in which the conditions of the tumours and the complications to which they had given rise were verified by operation. The object of the paper is to assist us in obtaining a more accurate knowledge of the life-history of these tumours than we at present possess, and, as Dr. Cullingworth points out, it is only by accumulating such a body of evidence that we can safely allow our judgment to be guided in determining the very difficult questions which these cases continually present. Dr. Peter Horrocks contributes a very instructive paper upon Contraction and Retraction of Muscular Fibres with special Reference to the Uterus. One of the co-editors, Dr. Berry Hart, reviews the present state of obstetric medicine in a most suggestive essay entitled "Obstetrics at the Beginning of the Twentieth Century: an Attempt at an Appreciation." The more strictly clinical material of the number consists of a paper on a Case of Tubal Pregnancy of Six Months' Development without Rupture of the Tube, by Professor W. J. Sinclair, and a Case of Fœtation in the Rudimentary Horn of a Bicornate Uterus by Professor Murdoch Cameron. Dr. Arnold W. W. Lea contributes a very complete critical essay upon Anæsthesia by Subarachnoid Injection of Cocaine in the Lumbar Region: its Use in Gynæcology and Obstetrics. A review of current literature, reviews of books, and the reports of various societies conclude the number. The whole consists of some 120 pages, is of large and convenient size (royal octavo), and clearly printed upon good paper. We would like to suggest, however, that the table of contents should be printed upon the back of the cover and not amongst the advertisements, as is done at present The chief editor, Mr. Alban Doran, and his colleagues are to be congratulated upon the prospect of future success which the first number of this journal foreshadows.

*The Journal of Physiology.* Edited by Sir MICHAEL FOSTER, K.C.B, F.R S., and J. N. LANGLEY, Sc D., F.R S. Vol. XXVII., Nos. 4 and 5. London: C. J. Clay and Sons. Dec. 23rd, 1901. Price 10*s*.—The articles contained in this part are as follows. 1. Dr. H. M. Vernon: the Conditions of Conversion of Pancreatic Zymogens into Enzymes, with eight figures in the text. Dr. Vernon shows that extracts of fresh pancreatic glands as a rule exhibit no ferment activity for some days and then suddenly develop nearly their maximum power. When the extracts taken from the pancreatic glands of different animals are mixed the ferment activity begins to develop at once. The glycerine extracts are more active than either the alcoholic or the saline, both in regard to their tryptic and rennetic values. 2 Dr. Henry F. Bellamy: On the Agents Concerned in the Production of the Tryptic Ferment from its Zymogen. 3. Dr. J. A. MacWilliam: Rigor Mortis in the Heart and the State of the Cardiac Cavities after Death, with two figures in the text. Dr. MacWilliam finds, in accordance with the statements of Starling, Bayliss, and Brunner, that there is a slight positive pressure in the cavity of the ventricles after death amounting to about two or three millimetres of mercury; during the rigor mortis of the heart this may rise to 30 millimetres of mercury The various conditions of the heart in asphyxia are given. 4. Mr. H. H Dale, B.A.: Observations, chiefly by the Degeneration Method, on Possible Efferent Fibres in the Dorsal Nerve-Roots of the Toad and Frog. Mr. Dale concludes from his experiments that the evidence is complete showing that there are no fibres which have their trophic centre in the spinal cord, at least in those dorsal roots which have been examined. 5. Note on the Percentage Composition of Egg-yelk, by Dr. John Malcolm The experiments show that the percentages of proteid fat and phosphorus in the yelks of eggs from the same hen are in very close agreement, whilst there are considerable differences in eggs from different hens, even when of the same breed. 6 The Spinal Roots and Dissociative Anæsthesia in the Monkey, by Professor C. S Sherrington, with a plate. In these experiments, performed on macaque monkeys, one or more dorsal spinal nerve-roots were divided, and the effect on the animals' sensibility in regard to impressions of heat, pain, and touch were noted 7. An Experimental Research into the Relations of the Posterior Longitudinal Bundle and Deiters' Nucleus, by Dr. E. H. Fraser. This article is illustrated by many figures in the text and demonstrates that the posterior longitudinal bundle plays an important part in correlating in accompanying her to Mexico. Her adventures, if never heroic, are always entertaining, her acquaintance is wide and acceptable, and her pages are well printed and profusely illustrated. As might be expected of a daughter of the late Dr. George Harley, Mrs. Tweedie has an eye for matters of medical interest. "Pinto," that curious tropical skin disease, allied to ringworm, meets her in numerous examples at various parts of the country. "A number of men," she says, "I met, with strange white or blue patches on their brown skins due to pinto, that much-dreaded disease, called by the natives *Saltsayanolitzth*. It is supposed that mosquitoes carry it as they do yellow fever and the Indians use a particular plant named *Isteneztil* for its cure, though the remedy does not usually prove very successful. Dr. Patrick Manson tells me he considers pinto contagious and doubts the Mexican theory of mosquito transport. There are four kinds of pinto—red, blue, indigo, and white, the last being the worst, for that means losing the pigments of the skin. In its early stage pinto can be stopped sometimes by cauterisation, but later mercury is required. Unfortunately, once it begins it is almost impossible to eradicate, and it often increases with alarming rapidity. The disease is hideous, something like leprosy, which also exists in Mexico, where it is not 'separated,' unfortunately." Had she been medical by training as well as by parentage Mrs. Tweedie might have made interesting pathological discoveries of the effects of tobacco if she had pursued the remarkable evidences that she met with of its early use. The Mexican baby apparently scorns the homely comforter or the toothsome coral Mrs Tweedie was wont to meet him with a full-sized cigar in his baby mouth. "'Does he often smoke?' I asked the mother in amazement. '*Si, señora*, he smokes three or four cigars a day; all our children have done so at that age' 'Does he ever let it out?' I asked. 'No, never,' replied his fond mamma, 'he would consider that a disgrace. He lights it himself and smokes it through.' 'Adaptability of temperament to climate!'" sagely reflects Mrs. Tweedie, and thus quits the subject. There is more in the matter than climate probably and less in the baby's mouth than met the eye. A Mexican cigar in Mexico and a "Mexican" in London are objects of vastly different potentiality. Mrs. Tweedie saw more peculiar sights than a smoking baby, but space does not permit us to do more than to recommend the perusal of her Mexican journeying to any of our readers who take pleasure in skilfully told travellers' tales.

*Anatomy in its Relations to Art.* By GEORGE MCCLELLAN, M.D. Philadelphia and London: W. B. Saunders and Co. 1901. Pp. 266, with 338 drawings and engravings. Price 42s

THE author of this sumptuous volume, who has had 12 years' experience as professor of anatomy in the Pennsylvania Academy of the Fine Arts, is entitled to speak with some authority on the requirements of art students, and on the whole we are in thorough agreement with him.

In his preface Dr. McClellan states that "only those parts are explained which would seem worth dwelling upon for art application." This is as it should be, yet the author hardly acts in accordance with his precepts, for throughout the book we find illustrations of the sphenoid bone, the base of the skull, mesial sections of the head and skull, together with diagrams of the prevertebral and scaleni muscles, as well as representations of the arrangement of the muscles of the suboccipital region.

Artistic anatomies, to use an expression applicable to all works of this class, are written either by anatomists with artistic tendencies or artists with anatomical sympathies. We naturally assume that Dr. McClellan belongs to the former category, and it is as an anatomist that we venture to criticise his work.

The author makes use of a large number of diagrams in illustration of the text. Now, a diagram, though of course it lays no claim to artistic merit, should at least be accurate. We regret to say that in many instances we have found these diagrams incorrect and in some cases absolutely misleading. To quote a few examples, we may mention Plate 20, where the parotid gland is represented as overlying the mastoid process and the insertion of the sterno-mastoid muscle; Plate 27, Fig 1, where there is a glaring error in regard to the insertion of the trapezius muscle; or Plate 40, Fig. 2, where the biceps is represented as lying on either side of the insertion of the deltoid muscle. We fail to see, also, what benefit the student is likely to derive from a study of Plate 24, Fig 2; from Plate 40; or from such figures as those represented on Plates 44 and 46 Nor is the text always satisfactory, despite the author's statement to the effect that the "matter relating to the bones and muscles is accurate though not exhaustive" It is hardly safe doctrine to teach an *art* student that the upper end of the radius does not play any part in the function of the elbow (p 22), nor can such a description of the origin of the infra-spinatus as this—"The infra-spinatus arises from the ridge on the scapula below the spinous process"—convey much to the mind of the student who will seek in vain for evidence of the existence of any such ridge. Surely, too, it was a mistake on the author's part to select for illustration, in such a work as this, a male skeleton displaying proportions in the upper limb akin to those of an ape.

To pass, however, from the purely technical to the applied aspects of the subject, we are glad to note a marked improvement in the character of the work. Dr. McClellan's chapters on the influence of the skeleton and muscles on the surface form, together with a brief account of attitude and posture on the "swing" of the figure, are interesting and instructive, the more so as they are abundantly illustrated by a valuable series of photographs of nude and draped models, admirably reproduced.

It is a happy idea on the author's part to represent side by side photographs of the model and the antique in similar poses, for such a device affords the student an admirable opportunity of comparing the one with the other and so enables him more readily to distinguish between the faults he should discard and the forms he must endeavour to realise.

## LIBRARY TABLE

*L'Epilessia Eziologia, Patogenesi, e Cura.* By DR. PAOLO PINI. Milan · Ulrico Hoepli.—No special work devoted to the important subject of Idiopathic Epilepsy having appeared in Italian literature for some years, the editors of the well-known Hoepli manuals have supplied the want by this monograph, in which the author has collected the recent, and especially the Italian, literature on epilepsy, and discusses in detail the etiology, the pathology, and more particularly the various methods of treatment of that condition. The social aspects of the subject are also dealt with, as well as the philanthropic schemes which have been set on foot in different countries for the benefit of epileptics

*Chimica Clinica* By Dr. RAFFAELE SUPINO Milan: Ulrico Hoepli. 1902—This volume of the Hoepli manuals, devoted to the subject of Clinical Chemistry, owes its value to the fact that it is written by a practical man with a long experience, in the capacity of assistant to the General Medical Clinic of Pisa, of laboratory methods and of the chemical operations employed in connexion with medical investigations The opening chapter gives practical hints regarding the most essential of these and succeeding chapters describe the most approved methods for conducting

## "The Islanders," and Some Considerations on Conscription.

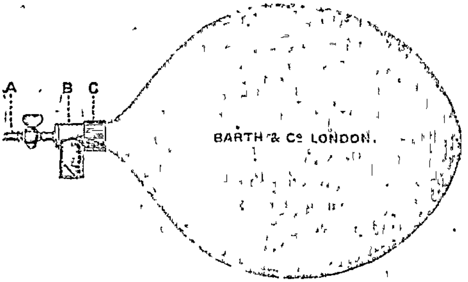
DURING the early period of the war in South Africa, when criticising the suggestion of conscription as a possible future means of increasing our army, we commended military training as an excellent thing, speaking from a strictly medical point of view. The young recruit learns discipline and self-sacrifice, and while, as a rule, he is well housed and well fed he is exercised so as best to develop his physical powers. These desirable ends are attained in no other calling, except of course in the navy, that is open to the youth of the humbler classes who has completed his school education. He may earn more money in other directions and will certainly enjoy more freedom, but the moral and physical benefits of a military training are undoubted. But conscription is a thing so foreign to the British cast of mind that its adoption in any rigid form is highly improbable. Various methods by which the strength of our army may be increased have been suggested and discussed since those dreary days when the ill-fortune of our arms in South Africa was so pronounced. And forms of conscription more or less modified are still freely talked of, but no political leader can hope to face the constituencies of the British Islands, and advocate even a modified measure for compulsory military service, with any expectation of success at the polls: so that it is vain to talk of conscription while it is practically certain that a majority of the voting members of the community will never be persuaded to sanction it. The Boer war began badly, had a second stage that was not by any means as successful as it promised to be, and has passed into a long and dreary struggle. No man worthy of the name of British citizen will forget that his country is engaged in this struggle and that lives are being daily laid down on the veldt; but as the ultimate issue is certain there is no reason why a panic of apprehension should change the national attitude towards a constitutional question. Moreover, the country is not unmindful that our powerful navy ensures us against effective invasion. Undoubtedly the nation is against compulsory military service.

There is, however, a form of compulsion that will direct young men towards military service while it is independent of Parliament; and this form may establish itself even among those to whom a system even distantly approaching that of France or Germany would be detestable—the compulsion of public opinion is meant. Public opinion is urging upon our young men the duty of training them- lves for the defence of their country, even though to do means to deny themselves other more pleasant diversions age when pleasure is most attractive. And with a view of arousing in this country some such spirit of patriotism, Mr. RUDYARD KIPLING has written, and the *Times* has published, his remarkably outspoken poem—"The Islanders." The author, however, seems greatly to have missed his mark and to be regarded by the public not only as a depreciator of manly pursuits but as a slanderer of his country. To our minds Mr. KIPLING'S poem constitutes a timely warning that without zeal strenuously exercised, and self-denial exhibited in a practical form, no European nation can hope to hold its own among its rivals. He has used unduly blunt language, and, in his desire to record the services of our colonies, has depreciated the mother of those colonies in a needless manner; but the admonishment was required—at least, we think so. The criticism evoked by "The Islanders" appears to deal with it largely as an attack upon sports in general and cricket and football in particular. Such criticism appears to us to be unfair. The two expressions "flanneled fools" and "muddied oafs" are to be regretted if only because they tend to obscure the real issue; but at the same time no man who has attained to years of reason and discretion will deny that cricket and football engross public attention to an absurd extent at the present day. We do not say that but for cricket and football a number of young men would have joined the South African army who have not done so, but certainly the ranks of our volunteers might well be recruited from among the devotees of athletic sports. To say, as certain of Mr. KIPLING'S critics have done, that some good cricketers, such as Major-General SPENS and Major POORE, have distinguished themselves in South Africa is beside the point. These are not men who have given up the best years of their lives to a game: they are men who have found leisure to play games while pursuing their profession. The bulk, however, of the most distinguished cricketers and football players of our public schools do not enter the army or any other profession that necessitates an early devotion to serious work. Some proceed to the universities, impelled by a school-boy enthusiasm to win further athletic distinction rather than by any desire for an academic career. Others, whether they go to the universities or not, handicap themselves for life through their desire to continue game-playing when they should be facing the manly task of earning a livelihood. But for the present exaggerated athletic craze, many of them might make good soldiers, or might, at any rate, devote some portion of their manhood, their strength, and their intelligence to the service of their country. As members of the regular army they would find themselves in the profession of all others in which bodily strength and activity, and the qualities developed by their school-boy pre-eminence at games, would aid them in the path to distinction. As volunteers they would find themselves compelled to forego some of the personal pleasures they now hold dear, and to substitute for games exercises which are at least equally healthy, and which might make them of greater use to their country. Their example would be of value in attracting to the opportunity for physical development offered by military training those who now find their principal amusement in watching the exertions of others, in calculating averages, and speculating upon the issue of cup-ties—a class ocular nuclei and anterior nerve-cells through Deiters' nucleus. 8. Caseinogen and its Salts, by Dr. W. A. Osborne, with one figure in the text. 9. The Respiratory Exchange during the Deposition of Fat, by Dr. M. S. Pembrey. The experiments were made on the marmot, which stores up much fat in its body in autumn and its respiratory quotient is then greater than unity. 10. A Contribution to the Chemistry of Proteids, by Dr. F. Gowland Hopkins and Mr. Sydney W. Cole. The part also contains the Proceedings of the Physiological Society for October.

# New Inventions.

## A PAPER BAG FOR CLOVER'S INHALER

THE use of the indiarubber bag in successive administrations of ether with Clover's inhaler as commonly practised is objectionable upon hygienic grounds. Apart from ordinary unwholesome conditions a patient might be suffering from tuberculosis or, as a possibility, even zymotic disease. Besides acting as a cage for microbes and bacteria the rubber bag, being a non-conductor, condenses moisture from the air breathed into it, and my impression is that if that moisture remained *in the air respired less irritation of* the respiratory organs would occur during, and as a result of, etherisation. In practice I have successfully substituted paper bags, a new one being used for each patient, for the indiarubber bag of Clover's ether inhaler. Paper bags may be used instead of rubber ones with other inhalers—e g., Ormsby's, or wherever rubber bags are used as respiratory bags associated with anæsthetics.



A, Tap for attachment of tube for supply of $N_2O$. B, Angle mount. C, Strong rubber band to hold the paper bag air-tight to the angle mount.

They will be *found more economical, especially to administrators* who may not have frequent use for anæsthetics and who often find the rubber perished when they require to use their apparatus after, it may be, a long interval. The practical advantages of the paper bag are: (1) hygienic excellence at small cost—about one penny; (2) moisture does not condense within it; (3) better preservation in any climate; (4) in use it maintains its position, whether empty or full, without tending to collapse completely; and (5) lightness and elegance—important considerations with a nervous patient. The bags should be kept dry and any accidental hole or tear may be readily patched with adhesive plaster. These bags are obtainable from *Messrs Barth and Co* of 54, Poland-street, W., who have been very obliging in the matter.

RICKARD W. LLOYD,
Lecturer on Anæsthetics, West London Post-graduate College; Anæsthetist to the West London and St Mark's Hospitals.

---

SUGGESTED VACCINATION OF TRAMPS.—At the meeting of the Exeter Corporation of the Poor held on Dec. 31st, 1901, a guardian drew attention to the danger of small-pox being spread by tramps and suggested that the board should compel them to be vaccinated, but the clerk said that the board had no power to enforce the vaccination of tramps.

# Looking Back.

FROM

## THE LANCET, *SUNDAY, JAN.* 11, 1824.

### ON BATHING.

(CONCLUDED.)

No. 5.

THE following experiment of the late Bishop of Llandaff has been thought much more conclusive in favour of the supposition that something is positively received from without. Dr. Watson gave a Newmarket jockey, previously to a race, a single glass of wine, which weighed little more than an ounce, and upon weighing him immediately after the course, he was *found to have increased thirty* ounces, although he had taken nothing more than the glass of wine, and notwithstanding that something considerable must have been lost by the pores of the skin. The *objector* to cutaneous inhalation replies to this curious fact, that the additional matter might have been taken in by the lungs, and that no decisive results can be obtained without instituting processes which shall take pulmonary exhalation and absorption into the account. Under this impression, Dr. Rousseau of South Carolina made the following experiment: he poured a phial of spirit of turpentine on a table, in a close room, and walked backwards and forwards for half an hour; at the end of that time he found that his secretions manifested most unequivocally that the system was impregnated with the material He then provided a long pipe which communicated with the external air; he breathed *through it, cautiously excluding*, all communication with the air of the room. He then again poured out the same quantity of the spirit of turpentine and found that no impregnation had been produced. He then immersed his arm in the same fluid for two hours, luting the vessel to the skin, so that no vapour could escape; and in this case also both his urine and perspiration remained without the slightest impregnation; as was the case likewise when he smeared his body with the spirit of turpentine, while he guarded against the inhalation of the vapour by the lungs Other experiments have been instituted with a view to ascertain, whether by immersion in the warm bath, the weight of the body is increased, and in those trials which have been marked by the greatest accuracy, the result seems unfavourable to the supposition of any fluid being imbibed through the epidermis.

*To the statement, however, that no increase of weight* follows bathing, the objection naturally and obviously suggests itself, that the absorption may be countervailed by the increased exhalation. In order to meet this objection, M. Seguin, an anti-absorptionist, dissolved in the water of the bath in which he made his experiments, substances which produce a specific effect when actually taken into the system. He employed the oxygenated muriate of mercury in solution, and while the epidermis was entire, he never perceived a single instance of salivation or mercurial influence. But in cases where a considerable portion of epidermis was injured or destroyed, the specific effects of mercury on the system was produced.

*Experiments are still, perhaps, wanting to establish either* the one or the other doctrine on an immovable footing; but we think, to say the least, that the doubts which have been thrown on the permeability of the outer skin to extraneous matter, are such as to make us cautious in believing that much efficacy can fairly be ascribed to medicinal baths (whether the impregnation be natural or artificial) beyond that which is derived from temperature applied in a liquid or aerial form. In instances of cutaneous affection, indeed, the case may be different, because *in most of these last disorders, the actual skin, and* therefore the mouths of the absorbents are brought into contact with the material employed—the epidermis or scarf skin being broken down in several points by the morbid action going on upon the surface; and when these cutaneous derangements happen to be manifestations of internal disorder, the impregnated bath may prove of service in two ways: 1st, by exciting new actions in the superfices of the body; and 2ndly, by influencing the general frame, so as to subdue the force of the morbific process, whence had emanated the *disease of the skin.* J. W.

designs for the proposed new courts we do not know, but the failure of the courts of the High Court of Justice to satisfy any but the most optimistic critics points to some difficulty in obtaining competent opinions as to the merits of an architect's design by those best able to judge of the practical requirements of the building to be erected. Criticism in the case of a law court should be directed to its fitness for the trials to be held in it, and as a matter of equal importance to its suitability as a living room in which large numbers of men and women will have to spend many hours at a time, while some of them will pass therein considerable portions of their working lives. Of these regular inmates the judges, owing to the elevated positions, speaking literally, which they occupy, are the most exposed to the heated exhalations arising below them. Some judges are indifferent to this, preferring a warm atmosphere that is foul to air that is purer but at the same time possibly cooler, and are also apparently unaffected by that which is distinctly injurious to their weaker brethren. Sir Henry Hawkins, for example, who is now enjoying a green old age as Lord Brampton, never, we believe, allowed a particle of fresh air to enter his court that could possibly be excluded, and the late Baron Huddleston had the same peculiar taste. These, however, are exceptions, and the majority of our judges, we feel sure, would be grateful for pure air and would certainly not deteriorate in health in consequence. At the High Court of Justice and in some country assize courts every effort is now made to provide it, but at the Central Criminal Court the promise of a future new building which has been held out for many years seems to have stood in the way of present reform or even of palliative measures. Handfuls of herbs, indeed, are laid on the ledge in front of the dock, on the judge's desk, and elsewhere as an interesting survival of bygone days when dried camomile, daisies, and fragrant leaves were considered to be prophylactic against gaol fever. No doubt the aromatic foliage offered a welcome variety to the stenches of Newgate Prison, but more is now required than sanitary bouquets. Modern judges, barristers, jurors, and witnesses, all of whom come into the court through no fault of their own, have a right to claim that their sojourn in it may be as little unwholesome as possible. If a better building cannot be provided for temporary use, which is highly to be desired, it is at least possible, as we have suggested, to improve the old one, and to prevent it from being overcrowded to a point at which the constant and effective renewal of its atmosphere amounts to an impossibility.

◆

# The Recent Situation at the Macclesfield Infirmary.

A large number of references to the recent situation at the Macclesfield Infirmary have been made in the lay press, and the majority of them seem to us to have been inspired by considerable ignorance of the real points at issue. We therefore think it right to return to the subject, both in case any of our readers should be labouring under similar misconceptions, and in order that the public may through their medical advisers properly instructed in the matter when occasion arises. The awkward position at the Macclesfield Infirmary—and how awkward it was may be judged by the fact that if two completely divergent views had not been reconciled by the 15th of this month the institution would have been left without a medical staff—was not due to general opposition on the part of the medical staff to the female practitioner. So to represent the matter is entirely unfair to the medical staff, the medical profession, and the medical press who supported the staff in their attitude throughout. The rights of women were not involved in any general manner whatever, although it happened that the sex of the junior house-surgeon was the reason that in the eyes of her superior officers disqualified her for her post.

There were two questions involved in the dispute between the medical staff and the governors of the infirmary: (1) What is the duty of a public institution towards its patients? and (2) What is the position with regard to the election of the junior medical officers that the medical staff ought to occupy? The medical staff having failed to recommend to the governors, for election as junior house-surgeon, Miss Murdoch Clarke, considered that her subsequent election by the governors was a distinct vote of want of confidence. The medical staff did not believe that in such an institution as the Macclesfield Infirmary a lady could adequately discharge the duties of junior house-surgeon. Certain classes of cases could not in their opinion be left to her ministrations in justice to the patients themselves; while to maintain at the infirmary a resident medical officer unable to deal with the whole routine work of the infirmary was not, they held, economical or fair to her colleagues. There were additional reasons which influenced them in the view that the election of a female medical officer to reside in the Macclesfield Infirmary was inadvisable, but with a reticence that was perhaps more delicate than prudent they laid no stress upon the matter. But others have spoken out since, and it has become clearer to the public now than it was while the dispute was acute, that the domestic circumstances, in which the resident officers of a small general hospital find themselves mutually placed are such as call for uniformity of sex. The medical staff, having these points definitely in their minds, decided that the institution would not be at its best state of public efficiency if a female resident medical officer was appointed, for it would not be able properly to meet its responsibilities towards all its patients. They thereupon expressed their minds in their choice of a candidate for the vacant post; but the governors disregarded the staff entirely and elected Miss Clarke. And this brings us to the more important question:—What position with regard to the selection of the junior medical officers, with whom they have to work, ought to be occupied by the medical staff? This is a matter which remains to be settled yet as far as the Macclesfield Infirmary is concerned. At the meeting of the governors at which Miss Clarke's resignation of her post was accepted, one of the governors, Mr. R. Brown, on whose sensible attitude in the matter we have already commented, proposed the following motion:—

> "That in view of the resignation of the junior house surgeon (Miss Annabella Murdoch Clarke), which has just been accepted, the governors, with the object of avoiding in future a repetition of the unpleasant experience of the past two months, hereby place on record their opinion, subject to the

of persons upon whom Mr. Kipling might well have specially emptied his vials of wrath and scorn.

If anything that Mr. Rudyard Kipling has written, backed by the weight of public opinion, should tend to lure the young men of the British Islands to regard a period of healthy training as soldiers as an essential portion of a young man's education great good will be done. Mr. Kipling will have helped Great Britain to the attainment of a better force for home defence than an army composed of, or leavened by, unwilling conscripts will ever be. The men who have served as volunteers will be healthier men and better citizens than if they had devoted their leisure to watching others compile record scores and win challenge cups, or even than if they had themselves won fame for a season by performing feats that another generation will surpass and forget. We regret that Mr. Kipling, who is a real patriotic force in the land, should have represented the inhabitants of these islands as profoundly indifferent to the national fame now that the day of peril is over; in his desire to do justice to the colonial contingents of our South African army he has ridiculously overstated their performance; while to frighten us into being volunteers he has forgotten the existence of our navy. But with these reservations we consider that his much discussed poem of "The Islanders" is a cry of timely warning. If he has made the cry too shrill for sensitive tympana, he is all the more likely to have aroused the sluggish sense of those who hear slowly or imperfectly.

## The Atmosphere of the Old Bailey.

Early in last year the prolonged trial of Bennett, the Yarmouth murderer, at the Old Bailey had as its consequence the indisposition of the Lord Chief Justice who presided at it. We called attention to this in The Lancet[1] and questions asked in the House of Commons elicited the reply that the building was under the control of the City authorities, to whom the site of Newgate Prison was to be handed over for the construction of a Central Criminal Court more worthy of the metropolis of England. The date for the commencement of this work was not indicated and we are not aware of any visible signs that it is in progress or that its inception is any nearer than it was nine months ago. Since then the trial of the Horos case has been followed by the indisposition of Mr. Justice Bigham, and it is still possible that before a new court has been built the loss of valuable life may be the price paid for the dilatoriness and lack of proper precaution exhibited by the civic authorities. They have had plenty of warning. The Bennett trial was not the first occasion on which attention has been directed to the evil atmosphere of the Old Bailey. It was, however, a typical instance, and Dr. Holman, a personal friend as well as the medical attendant of the Lord Chief Justice, and himself a frequent visitor at the court during crowded trials, expressed strongly in public the opinion that the foul air inhaled during the six days that this case occupied was the cause of Lord Alverstone's illness. His view was confirmed by Sir Richard Douglas Powell, but nothing has been done.

The court is admittedly a bad one—bad for the purpose to serve which it was built—namely, the trial of prisoners—and bad from the point of view of sanitary science—a matter which no doubt did not largely occupy the mind of its architect. It is not, by the way, the court in which in 1750 two judges, the Lord Mayor, and about 60 jurors and others caught "gaol distemper" and died; nor is it, as that court was, subjected to the pestiferous influence of a contiguous prison filled with malefactors and debtors huddled together in circumstances of filth and disease that we can hardly realise in these more enlightened days. It is, however, a court ventilated by windows at each end, which cannot be opened during the sitting of the court because at the one end they are immediately over the heads of the jury and at the other almost as close to the representatives of the press. A judge might disregard the convenience and remonstrances of the latter, but he could not hope to bring his trials to a proper issue if he insisted on the former being subjected to draughts against which they would inevitably protest. As a result the windows of the particular court at the Old Bailey of which we are speaking are usually opened during a day's sitting for about half an hour in the luncheon interval, or for less time if the judge chooses to give, as judges have been known to do, orders to that effect. There is either no other outlet for foul air than the windows, or none of any substantial value; while such "fresh" air as from time to time may find its way into the court does so through doorways opening on corridors or from the premises below the dock, up the stairway by which the prisoners enter; but in the absence of any established exit for the air the atmosphere can hardly be replaced in appreciable quantities. Meanwhile, in sensational cases the usual audience is increased by eager spectators from the general public, some privileged to occupy seats (that is to say, introduced by the authorities to whose custody the court and the health of those in it are entrusted), some being barristers in robes, some pressmen and artists, and others, perhaps, jurors in waiting. The result is that, instead of only the seats being occupied which the architect designed for those destined to be present at trials, every inch of standing room is filled by persons who not only breathe and re-breathe the foul atmosphere, but also appropriate many cubic feet of space which otherwise would at any rate be filled with atmosphere of some sort. There are, therefore, two points to which the attention of the city authorities may well be directed, should they consider it worth their while to protect those whose duties take them to the Central Criminal Court. The ventilation of the courts, or of the particular court most liable to be overcrowded, should be improved as far as it is possible by temporary measures not necessarily involving a large pecuniary outlay. Steps should also be taken to avoid overcrowding by limiting the number of those admitted to the seats above and below and by forbidding the filling of the gangways with spectators. It may here also be pointed out that, unless such steps for the preventing of overcrowding are to be taken in the future, the architect of the proposed new courts should be instructed that his scheme for providing them with fresh air must take into account the fact that every inch of the floor, and not only the seats which he has introduced into his plans, will be liable to be filled by the audience.

What measures may have been taken with regard to the forms of pneumonia are in future to be discriminated, the croupous or lobar being separated from the catarrhal or lobular forms, and these forms, in their turn, being separated from the epidemic or infective type of that disease. The italicised terms, "puerperal fever," "gastro-enteritis," and "convulsions," similarly come under condemnation, and it is to be hoped that in future they will be used but sparingly. We have said enough to show that pains have been taken to render the new weekly return as serviceable as possible, and we trust that medical men generally, as the authorised certifiers of cause of death, will assist the authorities at Somerset House to improve to the uttermost our national system of vital statistics.

---

## THE RELATION OF THE CHURCH TO SANITARY REFORM.

A STORY is told that a Local Government Board inspector who was sent to a provincial town in consequence of an outbreak of small-pox met amongst others the rector of the parish who, being anxious to promote the physical as well as the spiritual welfare of his parishioners, asked how he could assist matters. The inspector, noting the profession of his interrogator, drily remarked: "*Preach vaccination and revaccination.*" On the following Sunday the rector dilated upon the blessings of science in general and upon those of vaccination in particular, and on the succeeding Monday morning the public vaccinator was besieged by those anxious to follow their pastor's advice; so much so, indeed, that the lymph running out a riot was only with difficulty prevented. This little narrative is illustrative of many which might be told of the signal service which the clergy of all denominations have from time to time rendered on occasions of danger to the public health. Nevertheless, the assistance of the clergy might, we think, be more generally accorded than is the case at the present time The opportunity of the clergy for utilitarian work of this description is, indeed, unique. Each Sunday a very considerable proportion of the population finds its way to some place of worship and this material fraction of the whole population reacts to some extent upon the remainder who, whether from indifference or for other reasons, do not often darken the doors of our churches and chapels. But even the indifferent are in no sense positively hostile to the Church, and many of them would gladly welcome any effort by which the work of the clergy might be turned into practical channels such as are here in question. We do not for a moment suggest that at festivals such as Christmas the doctrine of cleanliness should be substituted for the higher theme of peace and goodwill, but if the clergy would from their pulpits now and again urge upon their congregations the blessings of cleanliness, fresh air, and light a force would be brought into operation the results of which would soon become apparent. Not only could the clergy do this from their pulpits, but they could in their intimate and trusted relations with the poor in their homes instil into them the doctrines of health. There is no body of men more fitted to assist in bringing about a better housing of the poor than the clergy, who, by teaching the people to open their windows and to seek the light, would gradually elevate the dirtier classes to a desire for better dwellings and an unwillingness to occupy dilapidated and ill-ventilated property. In this way the clergy would indirectly assist the sanitary authorities and medical officers of health, and would help to bring about the return of men to local authorities and to Parliament who would see that the housing problem received adequate attention. There is, too, another direction in which the clergy are in a position to promote reform Churches, many of them at least, were erected at a time when the [illegible] of ventilation was but little attended to, and hence [illegible] about that the atmosphere of these places is very often during divine service either eminently oppressive from the accumulation of organic products, or altogether unbearable by reason of the draughts which abound. The clergy would be doing a good work were they to appoint through Convocation or some other body a commission to investigate the matter and to report thereon. Finally, there is still outstanding the old and somewhat threadbare subject of the communion cup. We refer to this matter with due reverence and with the true interests of the Church at heart It must be borne in mind, however, that amongst those who gather together at the altar-rail are likely to be found some who are in feeble health and who are perhaps afflicted with communicable disease of a subacute or chronic type It has also to be pointed out that, according to the rubrics in the Prayer-book of the Church of England, the officiating priest must consume such of the consecrated elements as are left over and above the requirements of the communicants. That an element of risk is recognised by that Church itself is obvious from the fact that in the case of private communion of a sick person such sick persons have to communicate last. We do not propose to discuss here whether or not drinking from the common chalice is in the view of the Church a custom necessary to be retained—in the Roman Catholic church communion in one kind alone is employed for the laity—but we should be glad to see the question seriously faced by the Church itself, rather than that the necessary reform should be enforced from outside or that a partial abstention should result.

## THE INVESTIGATION OF CANCER.

WE have received from an evidently well-meaning correspondent a request that publicity should be given in THE LANCET to the announcement that a "cancer statistical bureau" has recently been formed in London with the object of undertaking a crusade against that disease. We are further asked to insert a circular and list of some 25 questions which the bureau desires to be answered by friends and others having special opportunities of furnishing general information respecting cases of malignant disease. We need hardly say that any judiciously directed attempt to increase the sum of human knowledge concerning this most intractable scourge will always receive sympathetic consideration at our hands; there are, however, certain fundamental conditions which are essential to the success of such an undertaking as the present, and which appear to be lacking in the scheme before us. We may at once declare that there is no problem within the domain of science which is more closely beset with difficulties than is that of the natural history of malignant disease. Accordingly we should have expected in the circular referred to some assurance that the persons undertaking the investigation possessed a competent acquaintance with scientific medicine. As, however, we can find no indication of the kind, and as moreover the name of the gentleman who addresses us does not appear in the Medical Directory, we must assume that the Cancer Statistical Bureau is exclusively composed of laymen. In a leading article in THE LANCET of August 31st last we strongly urged on the Government the appointment of a Commission to investigate exhaustively, and therefore necessarily under medical direction, the whole question of the etiology of malignant disease; and we further expressed the hope that inasmuch as His Majesty the King had publicly signified to the medical profession his earnest desire that such an investigation should be undertaken prompt effect would be given by the Government to the King's gracious request We deeply regret that although many months have elapsed since the period referred to, yet another year has closed and still no Commission has been appointed. It is to be hoped that when Parliament again meets next week pressure will be brought to bear upon the Government rules, as to the selection and election of senior and junior house surgeons—namely, that when a vacancy occurs it shall be advertised at least twice in the recognised medical journals, the applications for the vacancy submitted to the honorary medical staff, with a request that they carefully consider the same and select at least three, if possible, from which the governors shall appoint "

This motion fell to the ground because it found no seconder, but the matter cannot end there We are glad to observe that Mr BROWN gave notice that he would propose his motion at the next monthly meeting of governors When this occurs we trust that the governors will take Mr BROWN'S view and, within the limits of the considerable discretion which the motion allows, will grant the medical staff of the Macclesfield Infirmary a prominent voice in the choice of the resident staff Until matters are put upon some such satisfactory footing the infirmary may again become the scene of a quarrel that cannot conduce to its welfare

While we congratulate the medical staff upon a position which has allowed them to withdraw their resignations and to continue their work for the institution in an honorary capacity without loss of dignity, we sympathise with them in the trial that they have undergone and in the misrepresentations to which they are still subjected They have been, are being, and we fear will be, represented as selfish opponents to MISS CLARKE on the ground of her sex, as obstinate supporters of the old time doctrine that women should be kept to domestic work and should not be allowed to play a part in public life or to embark on a professional career Not one of the many journalists—we doubt if we should exaggerate if we said the many hundreds of journalists—who have written offensively of the medical staff of the Macclesfield Infirmary during the last month have taken the trouble to find out what it was to which the staff really objected in the behaviour of the governors The medical staff have been abused as selfish, ignorant fogeys, and we fear that they must not expect any large measure of redress MISS CLARKE, with whom both sides of the dispute sympathised, originally refused to assist either the medical staff or the governors by resigning, upon the ground that she was standing for a principle We presume that she recognised that the principle for which she was standing was not on the *tapis* We trust that here and there a few of our fellow journalists may also come to understand the inwardness of the dispute at the Macclesfield Infirmary, when we are certain that they will feel it their duty to make some amends to the medical staff for having depicted them as narrow self seeking misogynists They definitely declined to recommend MISS CLARKE to the governors for a resident post in the infirmary When the governors selected MISS CLARKE the medical staff were compelled to resign their offices, both in justice to themselves and in the furtherance of the best interests of the institution which they were serving

---

FREEMASONRY —The St. Luke's Medical Lodge of Instruction has been formed by a committee appointed by the eight medical masonic lodges for the use of medical Freemasons Meetings will be held at the Criterion Restaurant on the first and third Mondays in every month from October to May inclusive at 8 45 P M The first meeting will take place on Jan 20th Any medical Freemasons who may wish to join should apply to Mr G Rowell, 6, Cavendish place, W.

# Annotations.

"Ne quid nimis"

## THE REGISTRAR-GENERAL'S NEW WEEKLY RETURN OF BIRTHS AND DEATHS

JUST as we are preparing for press the Registrar General's return for the first week of the new year comes to hand and as it is in many respects a great improvement on former issues we think it worthy of a brief notice in our columns In the first place, we observe that the area covered by the return is now considerably enlarged the list of great towns for which statistics are given has been extended so as to include, in addition to Greater London, 74 other cities and boroughs in place of the 32 previously included Uniform particulars of mortality are now therefore published weekly respecting nearly one half of the population of England and Wales In the second place it will be seen that the tabular matter in the return has been re arranged so as to present the more salient facts in a manner as convenient as possible for reference But the improvement which seems to us the most important from a medical point of view is that which has been effected in the classification of diseases in Table 4 From the preliminary remarks in the return itself we learn that the list of death causes in the table referred to "has been modified, but that "care has been taken to preserve the means of comparison with the former list wherever this has been possible " In this table we notice several useful amendments For example, although the total number of death causes remains the same, several of the less important diseases included in the former list have been deleted and thus space has been obtained for the insertion of other and more definite diseases Again, we are pleased to observe that a note has been appended at the head of the table to the effect that certain of the terms retained in the list (presumably because they are still in use by some medical men) are printed in italics, in order to indicate that they are either the names of symptoms merely or are otherwise objectionable The italicised terms should therefore be used in medical certificates only in cases where more precise information is wanting Further we note that certain of the principal groups of disease have been subdivided in this table, so as to give opportunity for the more accurate classification of those causes of death which hitherto have been sometimes ambiguously returned For example, deaths from tuberculous phthisis are generally certified as from "phthisis" or "consumption' simply, which term include, according to the authorised nomenclature, other diseases besides pulmonary tuberculosis The more precise term is therefore inserted *in addition to* the term more commonly, but less correctly, employed So also, as an alternative for the old fashioned but most misleading term "tabes mesenterica tuberculous peritonitis" is suggested In the past tabes mesenterica has been held by some to include not only tuberculous mesenteric disease, but likewise atrophy, marasmus and certain other ailments attended by wasting which are not necessarily tuberculous in their nature The malignant group of diseases also has been subdivided so as to distinguish the ' carcinomata from the sarcomata," and both of these from the numerous tribe of diseases indefinitely returned as "malignant We believe that inasmuch as a large proportion of the deaths in London from cancer occur in hospitals where necropsies are commonly made, the medical officers of those institutions will gladly avail themselves of the opportunity now afforded to improve the statistics of this terrible disease For the rest we notice that the various died. The minimum was in 1900, when there were only 444 deaths. The average deaths in November from all causes is 902, but in November last year there were only 443 deaths. This is equal to an annual death-rate of 19·58 per 1000, and compares favourably with any town of the same size in any other part of the civilised world. The death-rate for the month of November in Havana has in the past often amounted to about 100 per 1000 per annum and the average for that month was 38 per 1000. Thus we have another and an excellent object lesson of what sanitation can do in a general way to reduce death-rates, supplemented, in this instance, by special measures against yellow fever.

## IS THE COAL-SUPPLY OF ENGLAND SERIOUSLY DIMINISHING?

IN a letter to the *Times* of Jan. 7th Professor Raphael Meldola expresses regret that the question of the waste of coal by imperfect combustion in grates, stoves, and factory furnaces has not been specifically included in the terms of reference of the recently appointed Royal Commission on Coal Supply. Everyone will share this regret with Professor Meldola, for the appointment of such a strong Commission of capable men would afford an excellent opportunity for dealing decisively and authoritatively with the question of smoke-polluted atmospheres and their prevention. But, as we suggested in an annotation last week, the Commissioners in dealing with the question of the immense waste of coal through defective ways of burning it, will surely be brought face to face with the question of the prevention of smoke, for smoke implies waste, and if the Commissioners succeed in showing how this waste can be prevented they will have indicated at the same time how the evil of smoke may be abated. There is little doubt, however, that primarily the Commission was appointed to determine the broad question of future resources and supply, having regard especially to the needs of the navy as well as of industrial processes. But we should be surprised if the Commissioners found that the question of the prevention of smoke could be avoided considering that in London alone it is calculated that there are discharged into the atmosphere daily some 18,000 tons of unconsumed fuel. That alone is eloquent testimony of the need for investigation.

## THE RESULTS OF PARTIAL GASTRECTOMY.

IN March, 1899, Mr. J. Rutherford Morison of Newcastle-on-Tyne showed at the Clinical Society of London five persons on whom he had performed partial gastrectomy for malignant disease of the stomach. In commenting on these cases we expressed the hope that Mr. Morison would later let the surgical world know the after-results, for obviously in several of them the interval after the operation was far too short to justify an opinion as to an absence of liability to recurrence. We are indebted to Mr. Morison for furnishing us with further particulars of these cases, which appear in this issue of THE LANCET (p. 86). In the first case pylorectomy was performed in 1897, and for nearly three years the patient was perfectly well, but signs of recurrence then appeared, a great part of the lesser curvature of the stomach was involved, and she died three years and two months after the operation. The second patient continued well for 18 months, but then he began to lose weight, and he died two years and two months after the operation. At the necropsy the neighbouring lymphatic glands and the liver were extensively affected by the growth. The third patient first had signs of recurrence eight months after the operation; a large swelling appeared in the epigastrium, and she died 15 months after the pylorectomy. In the fourth case the patient had perfect health for nearly two years, but then he had a febrile attack, and as he recovered from that signs of recurrence of the growth appeared, and he died 11 months later with a large mass in the epigastrium and an enlarged liver. In the fifth case gastric symptoms appeared about two months after the operation, and death occurred about six months after the pylorectomy. On a superficial consideration of these cases it might at first be thought that they were unsuccessful, for in every one of the five recurrence occurred either locally or in the liver. This is certainly true, but it must also be borne in mind that in all the cases there was a period of absence of symptoms, more or less lengthy, but extending in one case beyond two years. During this period the patients gained greatly in weight and were able to digest ordinary food. The lessons to be learnt from these cases are: 1. That malignant disease of the stomach is frequently more extensive than appears to the naked eye, for in most of the cases local recurrence took place. Therefore, a very wide removal of the growth is indicated and the experience of the last few years shows that large portions or the whole of the stomach may be removed without any serious disturbance of the digestive functions. 2. Since recurrence in the second case occurred in the lymphatic glands and in the liver though the stomach itself remained free it is obvious that these must have been affected before the operation. The only method of obviating such a result is to operate early and for the opportunity to do so the surgeon must be indebted to the physician who invariably sees these cases first. If an evident swelling in the epigastrium is awaited before a diagnosis of malignant disease of the pylorus is made a very large proportion of the cases will be too far advanced for complete removal of the growth, for the lymphatic glands and the liver will be already affected. So far as the surgery of Mr. Morison's cases goes nothing could have been better; from the operation itself recovery in all cases was speedy and complete, but the operations were undertaken at too late a date for the complete removal of the disease.

## SMALL-POX AND CHICKEN-POX.

WE have on several occasions referred to the difficulties which may arise in the differential diagnosis between small-pox and chicken-pox. Some of the metropolitan boroughs have already decided to make chicken-pox a notifiable disease under the Public Health Act and the council of the borough of Paddington has now decided to do likewise. The council also at the meeting held on Jan. 7th passed two resolutions: (*a*) urging the London County Council to put in force the powers conferred by Sub-section 6 of Section 56 of the Public Health (London) Act, 1891, with a view to making chicken-pox notifiable throughout the metropolis; and (*b*) to forward copies of the resolutions to the city and borough councils of the metropolis and to the councils of all the districts within Greater London. We also urge the public health committees of other boroughs to adopt a similar course. The addition of chicken-pox to those diseases which a medical practitioner is obliged by law to notify need not be a permanent one, but it might be enforced for a period of 12 months only or until the present outbreak of small-pox has subsided. A correspondent sends us an interesting account of a family attacked with chicken-pox. Three children, aged respectively six, four, and two years, suffered from varicella at the same time. Two of the cases were of the ordinary type, but in the eldest child the eruption was very profuse and the amount of constitutional disturbance which followed was characterised by feverishness and headache. There were well-defined ulcers in the mouth and on the fauces. The child had been successfully vaccinated. In all three cases there were no premonitory symptoms, the rash being the first evidence of anything ailing the children. About a fortnight after the rash appeared on these children the to secure that adequate investigation of this most important subject should be no further delayed. From what has been said our correspondent will gather that we think it inadvisable to attempt such a partial, and therefore insufficient, inquiry as that advocated by the bureau; and we do so mainly out of consideration for the feelings of relatives who may be called upon to supply the information asked for. The intrusion of such questions as those proposed at a time of actual or impending bereavement can be justified only on the ground that by such means future suffering may possibly be spared to others: and as we are satisfied that the scheme of the bureau will leave the main subject of the essential nature of cancer untouched we think it better that a competent scientific authority, such as the Commission suggested, should be empowered to deal exhaustively with the entire subject. We are therefore reluctantly obliged to say that we cannot give effect to the wishes of our correspondent.

## SANITARY WORK IN MANCHESTER.

OUR Manchester correspondent writes:—Defective drainage, with the nuisances and injurious consequences resulting from it, is one of the commonest facts and experiences of either town or country. Some years ago its supervision by the municipal authorities of Manchester was very imperfect, the work and the responsibility being divided between the sanitary and the paving and highways committees Reports as to nuisances from defective drainage received by the former were referred to the latter, who, when property owners failed to remedy the nuisance, stepped in and did the work, charging the owners with the cost. This was the theory but it failed in practice, for the highways committee could not cope with the work and many complaints of its shortcomings were made both by the public and by the medical officer of health In 1896 it was arranged that this inefficient system should cease and that the sanitary committee should take entire charge of the matter The house drainage sub-committee of the sanitary committee now superintends the house drainage department, which is an offshoot or extension of the sanitary department At first there were only three inspectors, then two more were added, and now there are seven at work in the city under the direction of the manager, while in the town-hall eight clerks are engaged in the work of the department. In a report issued in 1898 it was stated that 95 per cent of the drains examined were defective, while fully 80 per cent. were in a "deplorable" condition. Of the orders executed up to that time "over 35 per cent originated through death, fever, or other sickness on the properties concerned." To show the extent of the work it may be stated that during the financial year ending last March, a sum of £26,205 was expended on repairs, the number of houses dealt with being 5258 and of business premises and public buildings 894, making a total of 6152 The drainage of Manchester has always been supposed to be fairly good, though what to do with its products has seemed an almost insoluble problem But the revelations of the inspectors show, that though ignorance may be bliss, it is not folly to be wise. "Butt ended pipes" without sockets were common and as a consequence there were cesspools under houses One was found under a restaurant, 17 feet deep. Personally I remember a case of bad throat that occurred in a good house occupied by a well-known engineer who was quite sceptical as to anything being wrong with his drains But on investigation it was found that an old brick drain, filled with sewage matter, extended right under the house It will probably be some time before such things cease to be brought to light in the older parts of the city Now all pipes must be socketed and be properly fitted with cement and the work has to come up to a high standard. When a nuisance is reported a notice of 14 or 21 days is served on the owner or agent. If the necessary work has not been done by that time one of the sanitary inspectors visits and reports to the house drainage department. The owner is then advised that the corporation is about to do the work, and if this is not effective the contractor for the district is instructed to remedy the nuisance This is done under the close supervision of the inspector, and before the work is covered up the drains are tested thoroughly by the water test. All new drains, their course and condition, are marked on the ordnance map. The inspectors are all trained men who have passed a technical and practical examination There is no doubt that the department is doing work that will tend to improve the public health. Bad as the drainage has been in Manchester, it is probably quite as good as in other large towns throughout the country, so that an immense amount of work has still to be done before it can be said with truth, though it is often said in ignorant faith, that "our drains are all right."

## THE DIAGNOSIS OF SYPHILITIC INSANITY AND GENERAL PARALYSIS.

Dr. W. K. Walker, Dr. Theodore Diller, and Dr. R G Burns have published in the December number of the *American Journal of the Medical Sciences* an article which discusses the differential diagnosis of syphilitic insanity and general paralysis, with cases illustrative of the same. According to Fournier 21 per cent. of patients with tertiary syphilis developed cerebral affections of syphilitic nature, and in nearly all such cerebral cases mental disorder was present. The above named writers believe that "syphilis may be an etiological factor in the production of insanity through toxæmia or through exhaustion of the highest psychical centres from worry and anxiety." Such exhaustion, they say, might also result from venereal excesses, traumatism, alcoholic and other intoxications, and infectious fevers such as influenza. When the mental symptoms were at first uncomplicated with such manifestations as sudden faints, convulsions, paralyses, or optic neuritis, diagnosis of both syphilitic insanity and general paralysis was difficult, and the malady might be often overlooked and the hope of early treatment lost to the patient Whether the mental symptoms assumed a hypochondriacal, delusional, maniacal, or melancholic type they speedily tended to pass into dementia The following cases afforded practical illustration of the points of diagnostic importance

Case 1—The patient was a man, aged 35 years, whose parents were neurotic and "queer," and whose paternal and maternal relatives were tainted with insanity. Up to the age of 16 years the patient had suffered from violent attacks of intestinal colic. He was bright and intelligent when at school, but became addicted to excesses in drinking and smoking since the age of 18 years. He got readily and unduly intoxicated with small doses of alcohol. He contracted syphilis at the age of 18 years and married at 22, the union being unhappy and leading to a separation. In August, 1899, he sustained an injury attended with fracture of several ribs produced by a falling weight He had barely recovered from this when he contracted malaria, from which he suffered continuously for three months. He now became dazed and oppressed, had intense headache and insomnia, grew irritable and suspicious towards his friends, and had occasional outbursts of frenzy, during one of which he attempted to murder his wife In July, 1900, he had two "fainting spells" and began to suffer from hallucinations of hearing "music" An obscure febrile attack followed in which he seemed to be suffering from visual hallucinations of horrible objects He recovered from this attack, but recurrences took place twice afterwards (during September) square inch, a pressure which is found to be sufficient for fire-extinguishing purposes and thus to render the service of a fire-engine superfluous. According to the late Sir Edward Frankland, the water possesses an extremely high degree of organic purity and is of excellent quality for dietetic use. The Urban District Council of Portland, its engineer, and others may be congratulated upon having undertaken a work which has been thoroughly done and is well calculated to secure for the town the highest possible sanitary conditions and a satisfactory health return.

## GUY'S HOSPITAL.

ON Wednesday, Jan. 15th, there will be held at the Mansion House, under the presidency of the Lord Mayor, a meeting in support of the appeal on behalf of Guy's Hospital. There is no need for us to emphasise the good work done by Guy's Hospital, but, like nearly every other charitable institution in the kingdom, it is sorely pressed for funds. The very name "Mansion House" is synonymous with the word "alms" and we earnestly wish the meeting every success.

## THE SCHOTT TREATMENT OF CHRONIC CARDIAC DISEASE.

WE have received a copy of a pamphlet entitled "Personal Observations and Comments on Bad-Nauheim and the Schott Treatment," written by Dr. C. Turner of Butte City, Montana. The writer states that he made a prolonged stay at Bad-Nauheim and minutely studied the methods of treatment adopted at that resort. In this pamphlet Dr. Turner makes very serious charges against the professional ability and conduct of Professor Schott who holds a high place among the physicians of Bad-Nauheim. We understand that this pamphlet has been widely distributed and we think that Professor Schott should, in justice to himself and the many English physicians who send patients to Bad-Nauheim to be placed under his care, at once take steps to challenge, and we feel sure to refute, the grave professional charges which are brought against him.

## SANITATION IN INDIA.

THE principal article in the December number of the *Indian Magazine* consists of an address delivered on Nov. 25th, 1901, in the Jehanghir Hall of the Imperial Institute in London by Dr. Mohan Lal Dhingra, many of whose hearers were well acquainted with the conditions he touched upon, as the meeting was held under the auspices of the National Indian Association, and Sir George M. Birdwood, K.C.I.E., presided. Dr. Dhingra described his address as a humble attempt to claim for sanitation a place in the consideration of his countrymen and the Indian Government. He believed that the time had now come for the enactment of special sanitary legislation. In India it was practically impossible to control the numerous sources of water-supply, each house often having its own well, but if every town were provided with waterworks the people would soon take to this innovation and wells would fall into disfavour. Until this could be done wells should be placed under the control of municipalities with powers to enforce the roofing-in of wells and the protection of them all round with masonry. There was, he knew, a difference of opinion as to whether the populations of India were enlightened sufficiently for the introduction of such measures, but there could be no difference of opinion as to the necessity for an efficient sanitary service, and the first step in this direction would evidently be the appointment of a health officer for every important t He hoped that the time was not far distant when chools would be opened for the training of sanit nspectors, and when the Indian universities would grant minor sanitary diplomas. In the ensuing discussion Sir George Birdwood said that Dr. Dhingra's proposals would involve heavy taxation and would have to be enforced by penalties. In the prevention and cure of disease sanitary precautions and medical skill did not count for so much as the constitution of the individuals concerned, their habits, whether temperate or not, and their domestic and personal cleanliness. He thought that enthusiastic public health officers like Dr. Dhingra would do much more in support of village and municipal sanitation in India by appealing to the authority of the Code of Manu and similar law-books than by invoking the coercive interference of the State. He also related the case of a non-commissioned officer in an Indian regiment who had been under orthodox treatment for malaria and was apparently dying, but made a marvellous recovery after perspiration was induced by Brahminical incantations.

## THE MEDICAL DIRECTORY.

THE Medical Directory for 1902 has made its appearance promptly during the first days of the new year, and the publishers are to be congratulated upon their punctuality, which nothing short of a fire—as occurred two years ago—is known to disturb. The total number of practitioners for 1902 is 36,788, an increase of 434 over the total of 1901, which was 36,354. There are 6292 names on the London list, and 16,232 on the English provincial list. Scotland possesses 3645 medical men, as against 3569 in 1901, being an increase of 76; Ireland possesses 2587 medical men, as against 2575 in 1901, being an increase of 12; and Wales possesses 1183 medical men, as against 1165 in 1901, being an increase of 18. The lists of registered medical practitioners abroad, and of members of the Naval, military, and Indian medical services also both show a small increase upon the numbers of last year. The foreign and colonial names in 1901 numbered 3910, and this year number 3952, or an increase of 42; the members of the services in 1901 numbered 2798, and this year number 2886, or an increase of 88. The profession would seem, therefore, to have expanded evenly in all directions, and not in a greater degree than the increase in population ought to determine. The introductory article on the Principal Laws Affecting the Medical Profession, originally written by the late Mr. R. G. Glenn, is edited and revised this year by Mr. E. A. Armstrong. This article is not the least valuable part of an excellent book of reference, and we often have occasion to refer our readers to it.

## THE CONTROL OF PHTHISIS IN THE ROYAL BOROUGH OF KENSINGTON.

AS we foreshadowed in a leading article on the results of the British Congress on Tuberculosis, the several expressions of opinion which were then focussed in the shape of resolutions are already beginning to bear fruit. In London the first sheaves of the harvest are being gathered in by the Royal Borough of Kensington, and there is little doubt but that ere long other of our new boroughs will take action. The Sanitary Committee of Kensington has proposed, and the council has adopted the proposal, that cases of phthisis attended with expectoration should be notifiable, and consequently the medical practitioners of this wealthy and important district have been invited to notify such cases, the usual fee being paid for each case. The council has moreover arranged with the Jenner Institute for the bacteriological examination of sputum suspected to be tuberculous. On receipt of a notification the medical officer of health will determine whether or not the circumstances call for a visit from the sanitary staff, and we are glad to note that in this matter every effort will be made to coöperate with the attending practitioner. Rooms infected by tuberculous patients will be disinfected free of charge in all cases mother gave birth to another child who was born with four papules upon the body which developed into vesicles and ran the usual course without any further increase in number. Had the severe case above mentioned been an isolated one it might well have puzzled most practitioners as to whether it was one of chicken-pox or of small-pox.

## ARTIFICIALLY MATURED (?) WHISKY.

COUNTLESS attempts have been made from time to time to remove rapidly the raw characteristics of new whisky, but no real success has ever been attained comparable with the mellowing influences of age. The common and erroneous belief is that new whisky would at once be made as old if such things as fusel oil, furfurol, and probably other aldehydes could be extracted or destroyed. That is not the case. The product would then be simply alcohol and not whisky at all and spirits of wine might as well be consumed. It is constantly forgotten that genuine old whisky is palatable and wholesome because those very products which give it a raw, harsh, and disagreeable taste when it is young are the very constituents which time, and time alone, fashions into pleasing flavour. In fact, the harsher the taste when young the more full-flavoured is the whisky when matured. This salutary change is due to a gradual resolution of certain of the products of distillation, but not the alcohol, into new bodies which communicate to the whisky its characteristic flavour. These products, therefore, the aldehydes and higher alcohols, are essential to the production of a wholesome and good-flavoured spirit This result cannot possibly be gained by chemically abstracting these bodies as it is proposed to do. In fine old brandy the flavour is due essentially to these bodies assimilating each other, so to speak, over a long period of time and producing wholesome flavours. The ethers in particular, upon which much of the excellent medicinal effect of old brandy depends, increase largely with age and the ethers themselves are most probably a product of the union of the raw bodies. To eliminate these raw bodies, therefore, by a chemical process is to eliminate the materials which afterwards contribute the finest characteristics, and such a spirit cannot be regarded as being in any sense equivalent to a spirit mellowed by age. The process may take out deleterious things in a new spirit but it does not leave old whisky or old brandy behind and such extracted spirit would probably never be the better or more wholesome for maturing in the absence of those ingredients which make old spirit acceptable to the palate and the economy. The temptation to mature spirits artificially is, of course, very strong as storage represents so much capital locked up and some amount of loss by evaporation. But such artificial preparation can never be looked upon as fit to replace the spirit mellowed by age, and any attempt to substitute it is to be deplored and certainly on medical grounds to be discountenanced strongly.

## THE VON COLER LIBRARY.

WHEN in March last the late Inspector-General A. von Coler, the head of the medical department of the German army, was about to celebrate his seventieth birthday, it was resolved by a number of his friends, inclusive of many university professors besides military medical officers, to present him with a collection of works, all connected with military medicine, which should be entitled "The von Coler Library." Up to the present 10 volumes have appeared, but the list is not yet complete. The works published are as follows:—1. Kubler: "A History of Small-pox and Vaccination." 2. Buttersack: "Non-medicamental Therapeutics." 3. Transmann: "Operations on the Brain." 4. Fischer: "Operative War-surgery." 5. Zuntz and Schumburg: "The Physiology of Marching." 6. Köhler: "A History of War-surgery." 7. Behring: "Diphtheria." 8. Muschold: "The Plague." 9. H. Jaeger: "Cerebro-spinal Meningitis." 10. Gerhardt: "The Therapeutics of Infectious Maladies." According to a writer in the *Archives de Médecine et de Pharmacie Militaires* for December, 1901, von Coler is regarded as the reorganiser of the military medical service in Germany. It is owing to his energy that this department has undergone complete reconstitution since the Franco-German War. Amongst other benefits, the army owes to him the rehabilitation of its hospitals, which are now provided with all the requirements of modern science. To von Coler are also due the establishment of sanatoriums for convalescent soldiers and the institution of bacteriological laboratories. Under his rule German military medicine has increased in importance and widened its scope. By the creation of teaching centres, as well as by procuring the appointment of young medical officers as clinical assistants, he has opened out channels of instruction which heretofore were closed, thereby adding immensely to the efficiency of an important section of the war machine.

## THE ISLAND AND ROYAL MANOR OF PORTLAND.

COMMENDABLE steps have recently been taken in the quaint town of Portland to assure for its inhabitants and its visitors a clean bill of health. The drainage of the island was formerly of the crudest description, exposed sewers emptying into cesspools which were for the most part in a leaky and insanitary state. The sewers consisted of old stone drains which were originally open channels that from time to time were covered. In the scheme just recently completed at a cost of £25,000 some 20 miles of stoneware pipe sewers have been laid in such a way as to provide for an ample fall, no gradient being less than 1 in 150 at any point. The system is thus self-clearing. The drainage area comprises two districts, each having its own outfall. The first district discharges into West Bay into deep water, and from observations made in regard to the tide it was found that the sewage immediately on discharge was carried far out to sea The length of the outfall sewer is over 400 feet from the shore and it is constructed of heavy iron pipes with turned and bored sockets and spigots bolted together and supported on cast-iron piles. The construction of this outfall was carried on under considerable difficulty owing to the prevalence of heavy seas at the time. As it was the temporary plant and staging were washed away, but the sewer has been well and truly laid, inasmuch as it has been unaffected by the heaviest gales. For the purpose of drainage the town is divided into two districts. Some portion of the first district proved to be too low for the satisfactory discharge of sewage, and in such cases patent sewage lifts were used. In one instance the sewage from the high level part of the district is used in conjunction with air compressors for raising low-level sewage. In other cases water from the mains was used. The sewage from the second district is discharged through an iron pipe fixed in a line with the face of the cliff into deep water, and entering a strong current is rapidly carried seawards. The house connexions without exception are being laid by the urban district council's own workmen The sewers receive the drainage of the Admiralty hospital and works. A new hospital is shortly to be erected by the Admiralty at a cost of about £30,000. The water-supply of Portland is derived from a deep well in chalk 160 feet deep with headings 900 feet. The water is collected in a reservoir at Upwey which is capable of holding 550,000 gallons. A new reservoir is in course of construction at Portland which is to have a capacity of 600,000 gallons. The water is delivered from the Upwey reservoir through a 10-inch trunk main at a pressure of from 150 to 225 pounds per

# A DECADE OF PUBLIC HEALTH WORK IN THE ADMINISTRATIVE COUNTY OF LONDON.

## I.

WE have received from the medical officer of health of the administrative county of London a copy of his ninth annual report, which contains, in addition to an elaborate set of statistical tables with appropriate comments relating to the year 1900, a carefully written and most interesting history of sanitary administration in the metropolis during the first complete decade of the County Council's existence—a period which corresponds with the last 10 years of the nineteenth century.

Were we writing for Londoners alone we should at once proceed with our notice of this report, but inasmuch as so many of our readers reside outside the metropolitan area, and are consequently less familiar than ourselves with sanitary progress in London, we think it well to preface our review of the document before us with the following explanatory remarks.

The London County Council was constituted by Act of Parliament in the year 1888, and under the guidance of an illustrious chairman the first elected members of that body promptly set themselves to lay the foundation of that vast administrative system which has its present centre at Spring-gardens, and which ever since that year they have incessantly laboured to perfect for the benefit of their fellow-citizens.

At this stage it will be useful to recall the fact that up to the year 1888 the sanitary government of London had been distributed among 43 vestries, each of which exercised its functions (or refused to exercise them) according to its own will, exclusively and without regard to the welfare of adjoining districts and, indeed, without regard to the general welfare of the metropolis. Consequently, epidemics were free to spread from one metropolitan district to another simply from lack of suitable coördinating and supervisory machinery such as it is the principal function of a county authority to supply. Although for certain purposes of self-government London is subdivided under many independent authorities, nevertheless it is obvious that from a public health standpoint it must be regarded as one vast community, no part of which can suffer, either from epidemic visitation or from sanitary shortcomings, without imminent danger to all its other parts.

From the nature of the case it will readily be understood that many important preliminaries had to be arranged before the County Council could with propriety address itself to the formation of a public health department which should fully satisfy the requirements of London. For it is obvious that in order to meet such requirements a central health department must be so constituted that by successive developments it may be adapted to supervise, and where necessary to control, the sanitary functions of the various local bodies within its jurisdiction as supreme authority. Accordingly it was not until late in the year 1889 that the County Council took its first and most important step in this direction by appointing a superintendent medical officer of health.

On his appointment Mr. Shirley F. Murphy was unprovided either with office accommodation or with clerical staff. Perhaps fortunately for him, he was left to construct the new department mainly according to his own judgment, the necessary medical and clerical assistants and other requisites for the conduct of business being furnished at his special request. From the first his constant care has been to cultivate friendly relations with the local medical officers in charge of the 43 districts of the county, and by degrees he has built up what is practically an intelligence department or central bureau, to which communications may be addressed by his local medical colleagues, and from which they may derive expert advice or assistance in cases of difficulty or doubt.

It is only necessary to refer to the interesting series of reports already issued from Spring-gardens in order to show how completely Mr. Shirley Murphy has succeeded in his projects, as well as to indicate the thoroughly practical character of the work which is being done in connexion with the central bureau by the county medical officer of health and his able staff of professional assistants.

Coming now to an examination of Mr. Shirley Murphy's annual report for 1900, we find that as it is the latest so also it is in many respects the most interesting of the series of which it forms the ninth number. That this should be so is not surprising when we reflect that it treats of the health and sanitary condition of the largest urban community in the world—not for a single year only but for an entire decennium The administrative county of London is not only the largest; it is likewise, from a sanitary standpoint, the most perfectly equipped urban community of which we have knowledge For more than 10 years past it has enjoyed the protection of compulsory powers for the notification of infectious disease supplemented by a very complete system of hospital provision for the infectious sick. The arrangements for the isolation of small-pox are perhaps the most perfect at present existing within the British isles, for, instead of being treated in hospitals where they may readily become a source of danger to others, the small-pox patients are removed to hospital ships moored in the estuary of the Thames and at a safe distance from human habitation. London is divided into a large number of sanitary areas, each possessing its own medical officer of health and a complete sanitary staff, and so great is the importance which now attaches to accuracy of statistical method that for 10 years past every death occurring in a hospital, either in London or in a Metropolitan Asylums Board establishment in the suburbs, has been referred in the registers to the area in which the patient or inmate originally resided. Mr Shirley Murphy therefore enjoys exceptional advantages for the preparation of trustworthy vital statistics and for the compilation of sanitary reports, and we think that he has availed himself of those advantages very fully.

In the present report the annual rates of birth, marriage, sickness, and death for each year of the last decennium are set forth in great detail, the rates having been carefully corrected by the help of the census returns of population recently published. As in the earlier reports, so in the present, the statistical tables relate to the old sanitary districts of London As a matter of fact, these districts ceased to exist and were replaced by the new metropolitan boroughs on Nov. 9th, 1900, but for the purposes of this report it was obviously impracticable to do otherwise than assume that the old sanitary areas had continued in existence up to the end of the year.

In the county of London as a whole the rate of increase of the population has rapidly declined during the last 30 years; in the decennium 1871–80 the rate of increase had been 17·4 per cent., in the following decennium it fell to 10·4 per cent, and in the decennium just completed the increase did not exceed 7·4 per cent.

The space at our disposal will not admit of our following Mr. Shirley Murphy in his detailed examination of the metropolitan *general* death-rates for the year 1900; but we may note that the mean mortality of London during the decennium just completed was below that of 1881–90 at all periods of life from infancy to old age. Mr. Shirley Murphy reproduces a table, given in previous reports, by which he shows the mean annual number of deaths occurring in 1891–1900, as compared with the annual number that would have occurred had the death-rates of the previous decennium been maintained throughout 1891–1900. The number of lives gained and the number of lives lost at the several ages in the later period are also shown. This gain or loss is expressed in terms of "life capital," the figures being obtained by applying the "mean future life time" values, as ascertained from a London life table, to the number of lives gained or lost at each age group. According to this calculation we find that in the 10 years 1891–1900, as compared with the previous decennium, there accrued a saving of 3664 lives per annum, representing an annual salvage of 118,483 years of life capital. It is, however, important to observe that this reduction in the mortality has by no means been manifested in the death-rate from all causes alike Thus, for example, there has been in the later decennium, as compared with the earlier, a marked *increase* in the death rate from diphtheria, cancer, and influenza, and a slight increase in the death-rates from a few other causes. On the other hand, there has been marked *reduction* in the mortality from phthisis and also from non-tuberculous respiratory diseases and diseases of the nervous system, as well as a less strongly marked decrease in the death-rates from several other causes. Perhaps the most important of these changes for where death has resulted or where removal has taken place. Dr. T. Orme Dudfield points out in his circular letter addressed to all medical practitioners in Kensington that notification is especially necessary where good may be expected to accrue to the public therefrom. In addition to these precautions the leaflets of advice on the lines of those drawn up by the National Association for the Prevention of Consumption are being distributed, and Dr. Dudfield is careful to accentuate the importance of *wet cleansing in place of the dry and dust-disturbing methods* usually employed. This action on the part of Kensington, upon which Dr. Dudfield is to be cordially congratulated, emphasises the wisdom of the resolution on notification which was passed in the State Section of the British Congress on Tuberculosis, and subsequently confirmed by the Congress as a whole. There were some ardent spirits then present who would gladly have seen compulsory notification advocated, but in a matter of such far-reaching consequences as this, where the goodwill of the medical profession and of the public is essential to success, we are strongly in favour of going slowly, and for this reason we view with satisfaction the reasonableness of the Kensington programme.

## THE DEPARTMENT OF PUBLIC HEALTH FOR NEW SOUTH WALES.

WE have received a copy of a report of the Board of Health for New South Wales for 1898 The report is dated June 9th, 1900, and although it has therefore reached us at a rather late date the matter which it contains is none the less interesting. The usual vital statistics and the prevalence of the specific fevers call for no special comment. The work emanating from the biological laboratory, however, is well worth notice on account of the reports which are given of certain pathological conditions found in animals. For instance, there is a "Pathological Note on a Form of Blindness in Horses." This disease appeared amongst horses in the Darling river districts. When first affected the animals only showed defective vision in dim lights Horses whose sight seemed good in bright daylight were noticed to shy and to stumble in the evening after sundown. Later the sight became bad even in the daytime; the horses advanced cautiously with tremulous limbs and appeared as if frightened. No cases of total blindness were reported and the animals generally recovered after some lapse of time There was no external sign of disease of the eye. Except for the defective vision the animals appeared to be in good health. On examination of specimens of eyes sent to the laboratory the periocular connective tissue and the muscles were normal, and the bulbar conjunctiva and cornea were also normal. Mesial sections showed no abnormality of the coats of the eyeball or dioptric media Microscopical sections were made and transverse and longitudinal sections of the optic nerves showed fibrosis and atrophy of the nerve fibres. Individual nerve fibres of a bundle were atrophied, refused to take the stains, showed breaking-up of the myelin sheath into droplets, and granularity and interruption of the axis cylinders. Amongst other subjects dealt with in this part of the report are a "Preliminary Communication on the Etiology of Lymphadenitis in Sheep," "Observations on Epizootic Ophthalmia in Cattle," and the "Pathogenic Characters of Bacillus Typhi Murium." In an appendix to the report are some observations on the more common specific fevers: diphtheria, scarlet fever, and typhoid fever. A brief summary is given, in popular phraseology, of the nature of each disease, how infection may be spread, and the earlier signs of the disease. Directions are then given as to the precautions which should be taken to avoid infection. We recommend a perusal of these pages to our sanitary authorities as examples of leaflets which might be reprinted and widely distributed in times of epidemics. Unless a certain amount of education in these matters is afforded to the public the prevention of the spread of infection is rendered most difficult.

## SMALL-POX IN LONDON.

THE number of cases of small-pox in London increases day by day. On Saturday, Jan. 4th, there were 37 fresh cases notified and removed, on Sunday the 5th there were 33 fresh cases, on Monday the 6th there were 60 fresh cases, on Tuesday the 7th there were 53 fresh cases, and on Wednesday the 8th there were 33 fresh cases.

## THE DISTRIBUTION OF PLAGUE.

AS regards Egypt, during the week ending Dec. 22nd, 1901, no case of plague has been reported throughout Egypt, and the only case remaining under treatment, isolated at Ziftah on Dec. 7th, was discharged from the hospital as cured on Dec. 22nd. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on Jan 3rd states that for the week ending Jan. 2nd there were 34 cases of plague, of which 23 were fatal.

## METROPOLITAN HOSPITAL SUNDAY FUND.

AT a meeting of the Metropolitan Hospital Sunday Fund held at the Mansion House on Jan 7th under the presidency of the Lord Mayor, the Earl of Stamford was elected a member of the Committee of Distribution in the place of Mr. Lidderdale who retires in consequence of ill-health, and the Rev. C. H. Grundy was elected a member of the General Purposes Committee in the room of Sir Trevor Lawrence. Mr. R. B Martin, M P., and Sir Edmund Hay Currie were re-elected honorary secretaries and Mr. Henry N. Custance secretary.

AT the meeting of the Royal Medical and Chirurgical Society to be held on Tuesday, Jan 14th, the adjourned discussion of Dr. Sydney Monckton Copeman's paper on "Modern Methods of Vaccination and their Scientific Basis" will be opened by Dr. T. D. Acland. Amongst others who will take part are Dr. Sidney Coupland, Dr. Louis Parkes, and Professor Sims Woodhead. Dr. Copeman's remarks will be illustrated by lantern slides to be shown on Zeiss's epidiascope.

THE annual general meeting of the Harveian Society of London will be held at the Stafford Rooms, Titchborne-street, Edgware-road, W., on Thursday, Jan. 16th, at 8 P.M. The President, Dr. D. B. Lees, will deliver an address and the officers for the year will be elected. The meeting will be followed by a conversazione, at which will be shown illustrations of colour photography and a collection of British butterflies and moths by Mr. H. C. Phillips.

SIR W. O. DALGLEISH has offered to provide £5000 for building the new medical school for University College, Dundee and St Andrews University, and an additional sum of £5000 towards the extinction of the debt on the college. This last-named sum is offered on the condition that the balance of the debt—£7500—is forthcoming in a reasonable time

WE regret to learn that on Sunday, Jan 5th, Professor Virchow slipped in alighting from a tram-car and injured his hip. Everyone will wish the eminent professor as speedy a recovery as is compatible with his advanced years.

IT is announced that the donor of the sum of £200,000 for the King's Sanatorium is Sir Edward Cassel, K.C.M.G He is a well-known financier who was one of the pioneers in the development of modern Egypt.

point of view the year was less satisfactory than usual on account of a considerable increase of expenditure. The income was larger than in any previous year and there had been no reduction in the amount of charitable assistance received. The increased expenditure arose from various causes, the principal being an increase in household expenses, the high price of coal, a large addition to the assessment, and also the carrying out of many improvements. 16 of the patients admitted were deemed to be incurable, being chronic cases of long standing. During the year 18 patients were discharged as recovered, or 11·1 per cent. of the average number resident. "The length of residence of these patients had varied from three weeks in one case to 17 years in another. The latter was the case of a gentleman suffering from melancholia who for a large part of the time rarely spoke ...... and seemed to take no interest in his surroundings. Such occurrences of recovery after long periods of time are very encouraging." The deaths during the year amounted to 10, or 6·2 per cent. of the average number resident. The average age at death was nearly 75 years and the average residence in the Retreat was 15 years. One lady was 94 years of age and had been nearly 46 years in the Retreat. Of the deaths one each was due to phthisis, ovarian disease, and bronchitis, two each to cardiac failure and cerebral hæmorrhage, and three to senile decay. 13 voluntary boarders have been admitted during the year. One of them who was allowed to go out on parole attempted to drown himself in the river but was rescued by a policeman. He was subsequently placed under certificates. A newly admitted and violent patient secreted a match in the lining of his coat and when in the padded room he set fire to the cushions. He had the presence of mind to lie full length on the ground and to cover himself with mattresses and rugs and to breathe the fresh air as it entered under the door. The fire was speedily noticed and extinguished and the patient was rescued without having sustained any harm. The general health of the institution has been good except for one case of typhoid fever—affecting a nurse who, however, made a satisfactory recovery. Everything possible has been done to induce patients to occupy themselves usefully. "Patients doing regular work in the garden are paid by the hour, an arrangement which answers well. One patient earns sufficient to pay for his maintenance, whilst others keep themselves in clothes and pocket money." The Commissioners in Lunacy state in their report that the patients appeared to be well cared for and comfortable, and that the rooms and wards were in very good order, well aired, and comfortable. The committee of management state in their report that the sum of £130 has been received in donations during the year, and also a payment of £993, the final balance of a bequest under the will of the late Clement Jackson of East Hoe, Cornwall.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

FROM the commencement of the current year the Registrar-General's weekly returns will relate to the 75 large English towns which at the recent census contained populations exceeding 50,000. The aggregate population of these towns in the middle of 1902 is estimated to be 14,800,427. During the week ending Jan. 4th, 9695 births and 5707 deaths were registered in these towns, the deaths being equal to an annual rate of 20·1 per 1000 of the population. In London the death-rate was 20·6 per 1000, while it averaged 19·9 in the 74 other large towns. The lowest death-rates in these towns were 5·6 in Handsworth, 9·7 in Grimsby, 9·8 in Newport (Mon.), 10·2 in Coventry, 11·2 in West Hartlepool, 11·3 in Walthamstow, and 12·1 in Leyton; the highest rates were 24·3 in Brighton, 24·4 in York, 24·9 in Norwich, 26·4 in Sunderland, 27·3 in Merthyr Tydfil, and 28·1 in Tynemouth. The 5707 deaths in these towns included 510 which were referred to the principal zymotic diseases; of these, 157 resulted from measles, 83 from diphtheria, 80 from whooping-cough, 66 from scarlet fever, 51 from diarrhœa, 43 from "fever" (principally enteric), and 30 from small-pox. In Croydon, Tottenham, Walthamstow, Southampton, Nottingham, and 11 other smaller towns, no death from any of these diseases was registered last week; the highest zymotic death-rates were recorded in Hanley, Aston Manor, Preston, Rotherham, Stockton-on-Tees, and South Shields. The greatest proportional mortality from measles occurred in Norwich, Aston Manor, Preston, Rotherham, and South Shields; from scarlet fever in Birmingham, St. Helens, Middlesbrough, and South Shields; from diphtheria in Willesden, Reading, Hanley, and Middlesbrough; from whooping-cough in Birmingham, Leicester, Burnley, and Stockton-on-Tees; from "fever" in Great Yarmouth, Rochdale, Middlesbrough, and Stockton-on-Tees; and from diarrhœa in Tynemouth. 28 fatal cases of small-pox occurred in London, one in West Ham, and one in East Ham, but not one in any other of the 75 large towns. There were 754 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, Jan. 4th, against 506, 538, and 666 at the end of the three preceding weeks; 261 new cases were admitted during the week, against 134, 161, and 225 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 3033 and 3137 on the two preceding Saturdays, had declined again to 2987 on Jan. 4th; 313 new cases were admitted during the week, against 331, 247, and 263 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 427, 393, and 425 in the three preceding weeks, further rose last week to 452, but were 171 below the corrected average number. The causes of 86, or 1·3 per cent., of the deaths in the 75 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Portsmouth, Bristol, Manchester, Bradford, Leeds, and 38 other smaller towns; the largest proportions of uncertified deaths were registered in Ipswich, Birmingham, Liverpool, and Sunderland.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·7, 21·5, and 22·6 per 1000 in the three preceding weeks, further rose to 23·2 per 1000 during the week ending Jan. 4th, and was 3·1 per 1000 above the mean rate during the same period in the 75 large English towns. The rates in the eight Scotch towns ranged from 14·6 in Leith and 23·0 in Edinburgh to 25·0 in Perth and 27·2 in Greenock. The 750 deaths in these towns included 30 which were referred to measles, 12 to diarrhœa, 12 to whooping-cough, seven to "fever," five to diphtheria, and four to scarlet fever. In all 70 deaths resulted from these principal zymotic diseases last week, against 69 and 86 in the two preceding weeks. These 70 deaths were equal to an annual rate of 2·2 per 1000, which was 0·4 above the mean rate last week from the same diseases in the 75 large English towns. The fatal cases of measles, which had been 28, 30, and 36 in the three preceding weeks declined again last week to 30, of which 24 were registered in Glasgow, three in Dundee, and two in Greenock. The deaths from diarrhœa, which had been 15, 17, and in the three preceding weeks, declined again to last week, and included four in Glasgow, four Dundee, and two in Paisley. The fatal cases whooping-cough, which had been 10 and seven in the two preceding weeks, rose again last week to 12, which 10 occurred in Glasgow. The deaths referred to different forms of "fever," which had been 11, seven, and five in the three preceding weeks, rose again to seven last week, and included five in Glasgow and two in Paisley. The fatal cases of diphtheria, which had been three and eight in the two preceding weeks, declined again last week to five, of which two were registered in Edinburgh and two in Dundee. The deaths from scarlet fever, which had been two and seven in the three preceding weeks, declined again to four last week, and included two in Glasgow and two in Greenock. The deaths referred to diseases of the respiratory *organs in these towns, which had been* 188 and 166 in the two preceding weeks, increased last week to 182, and 77 in excess of the number in the corresponding period of last year. The causes of 41, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 17·9, 25·9, and 26 per 1000 in the three preceding weeks, further rose to 29·4 per 1000 during the week ending Jan. 4th. During the past four weeks the death-rate has averaged 25·0 per 1000, the

the worse is that which concerns that terrible malady cancer, the death-rate from which has increased during the last decennium by little less than 27 per cent. As His Majesty the King has publicly expressed a desire that the question of the causation of cancer should be investigated by competent persons, with a view, if possible, of checking its ravages, we can only express our astonishment that the Government has not as yet taken active steps with this object in view.

There is no single test of the healthiness of a community which is so generally trustworthy as that furnished by the rate of *infantile mortality*—*i.e.*, the death-rate of children under one year of age in each 1000 registered births. Infant life is peculiarly sensitive to the sort of insanitary conditions which generally abound in great centres of population. It is accordingly satisfactory to find from the present report that throughout the decennium ending with the year 1900 London experienced the lowest infantile mortality of any of the principal English towns save one—viz., Bristol, which has enjoyed an enviable notoriety in regard to low infant mortality for many past years. During the year 1900 the eastern group of metropolitan districts suffered the highest infantile mortality—namely, 175 per 1000 births; the northern group experienced the lowest, 145 per 1000; whilst the southern, the central, and the western groups experienced a rate of 158 per 1000. Among individual sanitary districts Holborn showed the highest rate (240 per 1000) and Hampstead the lowest rate—viz., 100.

# THE SANITARY CONDITION OF LEICESTER INFIRMARY.

As the result of a joint conference between the weekly board and the honorary medical staff of the Leicester Infirmary with respect to the recommendations of Professor W. H. Corfield as to the sanitary condition of the institution a report has just been issued of the decisions arrived at and it will be presented at the quarterly meeting of the governors to be held next week. The report candidly admits that the central block of the infirmary is old and structurally unsuitable for hospital wards, but urges that it is capable of conversion for administrative purposes. In regard to the wards the members of the conference agree with Professor Corfield that "certain re-arrangements and improvements are required," and that "the building would be greatly improved for the purposes of a hospital if it were divided into sections by means of cross-ventilated lobbies, as suggested in the plan prepared by Mr. Pick." The report states that the members of the conference agree with Professor Corfield's recommendations in reference to the nurses' bedrooms—that the nurses should be provided with a separate building—"as," adds the report, "entire separation from the wards must be beneficial to the health of the nurses." The report also supports Professor Corfield's recommendations for separate accommodation for infectious cases and for the out-patient department. In regard to the latter Professor Corfield stated that a separate building for out-patients "would considerably lessen the introduction of infection into the infirmary." With regard to the infirmary building in general Professor Corfield reported that "the floors are in most cases old and much worn" and that they required to be replaced with new ones, or covered with a parquet flooring, but the report of the conference points out that although in many parts of the house the floors require renewal none of the wooden floors are older than 1862, except possibly in the central block. Dealing with the question of the sanitary annexes and offices the report states that "a personal inspection of the various annexes and offices throughout the building shows that with the exception of St. Mary's Ward all the water-closets and slop-sinks are either new or have been renewed within the last 10 years. In most cases the iron and lead sinks in the ward sculleries have been replaced by sanitary earthenware ones, and the old baths have been replaced by new ones and others have been added. The particular pattern of the water-closet apparatus now in use has been called in question in the reports, but expert opinion appears to be divided as to the relative superiority of 'wash-downs' and 'wash-outs,' some modern institutions preferring one, and some the other. In each case much depends upon their being properly fixed and receiving systematic attention. The same remark applies to the question of 'tip-up' wash-basins." The "borough pattern" gully-traps, largely in use at the infirmary, are strongly disapproved of by Professor Corfield, but, adds the report, they have some distinct advantages for hospital purposes. Coming to the most important part of Professor Corfield's report—the state of the drains of the infirmary—the report says that "the drains, both internal and external, have been carefully tested, and in several cases faults have been discovered in the latter, and later investigation has disclosed that some of these faults were due to imperfect workmanship in fitting the drain-pipes to the iron outlets of the traps, thus allowing the escape of smells not through, but by the side of, the traps. There can be little doubt that in this way the atmosphere of the wards has from time to time been vitiated. The upper length of the drain most responsible for this state of things has already been entirely removed. Cases of imperfect connexion between iron and earthenware pipes were found in two instances on the western side of the building, which may have contaminated the hot-water duct near the nurses' dining-room windows. The escape from these faulty connexions has doubtless been injurious to the sanitary condition of the house, and instructions have been given to test, and if necessary to re-set, the whole of the gully-traps around the infirmary, and also to put additional ventilation pipes on the eastern block as recommended by Professor Corfield, and to make any other minor alterations in the existing upper connecting drain-pipes which may be thought advisable. The gully-traps have been regularly examined and cleansed and their satisfactory condition has been reported on from time to time at the weekly meetings. The drains have been systematically and thoroughly flushed. Those in immediate connexion with the buildings are receiving, and will continue to receive, careful attention. Sufficient cause has not been shown to justify Professor Corfield's opinion that 'the whole of the present drainage arrangements must be condemned and removed entirely and new drains laid on concrete ...... preferably throughout of heavy iron pipes, coated inside and outside with Dr. Angus Smith's solution and having the joints caulked with metallic lead.' This could only be carried out at a great expense which urgent need alone would justify." The concluding portion of the report of the joint conference sets out in brief the recommendations made by Professor Corfield and states that although doubtless many alterations and additions are desirable the weekly board and the governors will have to consider what is most urgent and really practicable, for to carry out the recommendations enumerated would entail an expenditure far in excess of any funds at present at disposal. The surgical staff having called attention to the utter inadequacy of the present operating theatre and the great difficulties under which the important and critical work of that department is carried on, the weekly board have ordered plans to be prepared for a new surgical wing, to comprise all the arrangements and appliances that the experience of the most modern hospitals has proved to be valuable. These plans have been adopted and the work is now making rapid progress. The new wing will contain two operating theatres (with anæsthetic, sterilising, and nurses' rooms), a waiting hall, a new surgery and two examination rooms adjoining, a dispensary and ample store-room, a room for special night cases, a sitting-room and bedrooms for the house surgeon and resident surgical staff, an entrance hall, a clerk's office, a porter's room, and sanitary and other requisite accommodation. The cost of the new wing will be about £12,000.

# ASYLUM REPORTS.

*The Retreat, York (Annual Report for 1900).*—The York Retreat was founded early in the nineteenth century by the Society of Friends for the care and treatment of insane patients and is one of the oldest institutions for the treatment of mental disease in England. The average number of patients resident during the year was 162 and comprised 60 males and 102 females. The admissions during the year amounted to 39—viz., 17 males and 22 females. Of these, 31 were first admissions. Dr. Bedford Pierce, the medical superintendent, states in his report that from a financial injury, giving a ratio per 1000 of strength of 688·9 and 135·2 respectively. The daily average of patients was 799·8, and the ratio per 1000 of strength 34·8, as compared with a daily average of 645·8 and a ratio per 1000 of 32·1 for 1899. The number of persons invalided from the service was 695, a ratio of 29·2 per 1000 of force, classified as 586 invalided for disease and 109 for injury. During the year there were 211 deaths, the death-rate per 1000 of force being for disease 5·01 and for injury 3·87, or a grand total of 8·88 per 1000. The admissions to the sick list during the year included 1699 cases of epidemic catarrh, 983 of malarial diseases, 963 of wounds, 902 of diarrhœal affections, 828 of rheumatic affections, 336 of dengue, 246 of alcoholism, 195 of dysentery, 175 of typhoid fever, 160 of measles, 132 of mumps, 128 of heat-stroke, 117 of pulmonary tuberculosis, 100 of organic heart disease, 99 of pneumonia, 40 of nephritis, 37 of rubella, 10 of small-pox, two of yellow fever, and one of bubonic plague. The returns of recruiting show that a total of 25,081 recruits were examined, of whom 9625, or 383·7 per 1000, were rejected for all causes, and 628, or 25·0 per 1000, were rejected for colour-blindness. A special appendix to the report, occupying 24 pages and drawn up by Dr. Presley M. Rixey, Medical Inspector, United States navy, is devoted to the case of the late President McKinley.

### AFFAIRS IN SOUTH AFRICA.

The War Office return of the casualties in the Field Force in South Africa during the month of December, 1901, shows the total reduction of the military forces up to the end of that year through the war to have been 24,299, made up as follows: deaths in South Africa, 931 officers, 18,033 men; missing and prisoners, 442 officers and men; invalids sent home who have died, seven officers and 449 men; and invalids who have left the service as unfit, 4437. As regards deaths (exclusive of those who have died in captivity) described as killed in action or died from their wounds we find the numbers to be 630 officers and 6397=7027, as compared with 11,273 deaths from disease The number of officers sent home as invalids amounts to 2664, and of men 61,666. Of these, a great majority have recovered and rejoined for duty; of the rest, 449 have died, 4437 have been discharged the service as unfit, and 862 are in hospital. As regards the purely military news it seems clear that De Wet had a strong force of excellent fighting material in his audacious and enterprising, as well as skilfully executed, attack on the British at Tweefontein. It was a disastrous attack as far as we were concerned and does not, we fear, say much for the alertness and foresight of the British force. The slanderous and unfounded charges against British officers and soldiers in the continental, and especially the German, press have naturally caused a good deal of indignation in this country.

### DEATHS IN THE SERVICES.

Surgeon-Lieutenant-Colonel Henry Cramer Guinness, L.R.C.P., L.R.C.S. Irel., A.M.S. (retired), at his residence, Wellington Lodge, Cheltenham, on Jan. 2nd, in his sixty-fourth year. The deceased, who was the son of the late Dr. Arthur Guinness, took the qualifications of L.R.C.P. and L.R.C.S. Irel. in 1859. He entered the army as an assistant surgeon in 1859 and was promoted to the rank of surgeon in 1873, surgeon-major in 1875, and surgeon-lieutenant-colonel in 1879. The deceased officer retired from the army on half-pay in 1893.

Colonel Oswald Gillespie Wood, C.B., R.A.M.C., who is reported to have died on Jan. 3rd at Kroonstadt, where he was principal medical officer, was in his fifty-fifth year, and was appointed a lieutenant-colonel in the Royal Army Medical Corps in March, 1894, after about 20 years' previous army medical service. In 1882 he served with the first Egyptian expedition and was at Tel-el-Kebir; in 1889 he was senior medical officer with the British troops engaged in operations on the Nile; and in the present campaign he was for some time in charge of a general hospital before taking up the post which he last held. Colonel Wood's South African services have been mentioned in despatches and they obtained for him the C.B.

### THE CHANGES IN OFFICERS' UNIFORM.

It seems an extraordinary thing that whenever an outcry rightly or wrongly is raised in this country in regard to the reform of the army, the War Office, or the Horse Guards authorities steps are taken, often without any apparent reason, to bring about, under a real or alleged idea of economy, some change of uniform or dress reform. There is no finality about anything and least of all about officers' uniform. The latest of the many regulations which have been issued on the subject will affect officers of the Royal Army Medical Corps in common with those of all other branches of the service. That the ultimate result of the new orders will be one of economy may be true, but that its immediate effect is to put officers to much expense in the meantime cannot be doubted and we hope that ample time may be given to allow of the present uniform being worn out instead of having to be cast aside as obsolete or not up to date. We may add that the new Army Order just published regarding the service dress of the army, which is a long and elaborate production, seems to be sensible and good and to have been carefully drawn up.

Captain Ernest Kinloch Johnstone, M.D., L.R.C.S. & P. Edin., lately assistant-surgeon, has been promoted to major and surgeon and is serving with the United States Army in the *Philippines*. *He is acting as chief surgeon of the* 3rd Military District, Northern Luzon.

"Audi alteram partem."

## INERT VACCINE LYMPH.

*To the Editors of* THE LANCET.

SIRS,—I have read with interest the letters which have recently appeared in your pages on the subject of inert vaccine lymph. Opinions appear to be divided on the subject, some of your correspondents suggesting that every practitioner should publish the results of his vaccinations and revaccinations, giving the source of the vaccine lymph employed; others incline to the view that the State alone should manufacture and distribute the glycerinated pulp; and others, again, would like to see a committee of experts appointed by the State to supervise private establishments *and to lay down the best methods of preparation and pre*servation of vaccine. I do not believe that the remedy is to be found in any of these proposals and I shall indicate what I consider is the remedy further on. To make use of the publicity afforded by the journals for the purpose of calling attention to certain marks of vaccine which have given good results or none at all would, I submit, be illegal. Moreover, a particular institution may conceivably supply an excellent vaccine at one time and a very inferior one at another. A monopoly of vaccine by the State would be like the monopoly of matches in France, where it is a saying: "They won't light, they are Government matches." A monopoly of vaccine, indeed, would be a much more serious matter than a monopoly of matches. There must be a method of manufacturing matches which is invariably successful, whereas there is nothing of the kind for the manufacture of vaccine. If a match will not light it is due to a defect in the process of manufacture or exposure to damp. In respect of vaccine the procedure may have been faultless, the lymph may not have been exposed to too high a temperature (heat being for vaccine what damp is for matches), yet the results may be negative. It follows that if the State undertook the exclusive manufacture of vaccine it is quite possible—indeed, it has actually happened—that for some considerable time the State may find itself in the position of being unable to furnish a trustworthy vaccine. So long as the field is left open to private institutions England will never, during such period, be left destitute of vaccine, since even public vaccinators can obtain a supply from institutions which, at that particular period, are in possession of an active vaccine. The French Academy of Medicine supplies lymph gratis to all practitioners who apply for the same, yet many prefer to obtain their lymph from private establishments on account of the failures following the use of the Academy lymph. *If the* State monopolised the manufacture of vaccine lymph it ought logically to monopolise the manufacture of all serums and even of all drugs. The State would become manufacturer of chemical products, druggist, herbalist; it would supply the retail chemists who would themselves become servants of the State.

There is no obvious reason why medical men should not in their turn become administrative officers and be constrained to take the opinion of their hierarchical superiors on the applicability of a particular remedy to a particular disease Following in the steps of medicine and pharmacy, industry rates during the same period being 19·6 in London and 21·1 in Edinburgh. The 214 deaths of persons belonging to Dublin registered during the week under notice were 21 in excess of the number in the preceding week, and included nine which were referred to the principal zymotic diseases, against 15 and 10 in the two preceding weeks; of these three resulted from diphtheria, three from diarrhœa, two from "fever," and one from whooping-cough. These nine deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 1·8 in London and 0·3 in Edinburgh. The deaths from diphtheria, which had been three and two in the two preceding weeks, rose again last week to three; the fatal cases of diarrhœa corresponded with the number in the preceding week; while the deaths referred to different forms of "fever," which had been four and five in the two preceding weeks, declined last week to two. The 214 deaths in Dublin during the week under notice included 33 of children under one year of age and 65 of persons aged upwards of 60 years; the deaths of infants showed a marked increase upon the number in the preceding week, and those of elderly persons were slightly in excess. Nine inquest cases and six deaths from violence were registered; and 65, or nearly one-third, of the deaths occurred in public institutions. The causes of 13, or more than 6 per cent., of the deaths in Dublin last week were not certified.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon E. W. Luther to the *Majestic*. Surgeons: J. R. Muir to the *Vivid* for dental duties; J. M. H. Conway to the *Jupiter*; W. B. Maurice to Haslar Hospital; H. C. Adams to the *Resolution*: M. L. M. Vaudin to the *Espiegle*; and W. Jackson to the *Wildfire* for the *Immortalité* and Naval Barracks.

### ARMY MEDICAL SERVICE.

Lieutenant-Colonel A. Keogh, C.B., R.A.M.C., to be Deputy Director-General and to have the temporary rank of Surgeon-General whilst so employed, vice Surgeon-General H. S. Muir, C.B., whose period of service in that appointment has expired. Dated Jan. 1st, 1902.

Colonel Sir T. J. Gallwey, Principal Medical Officer of the Home District, has been selected for appointment as Principal Medical Officer in India, with the rank of Surgeon-General, succeeding Surgeon-General W. Taylor, appointed Director-General of the Army Medical Service.

### ROYAL ARMY MEDICAL CORPS.

Temporary Major C. Stonham, C.M.G., Surgeon-Captain, Middlesex Imperial Yeomanry, is granted, on relinquishing the appointment of Officer in Command and Chief Surgeon, Imperial Yeomanry Field Hospital, the honorary rank of Major in the Army, with permission to wear the uniform of the corps. Dated May 2nd, 1901.

Surgeon Captain C. N. Lee, A.M.R., assumes medical charge of troops, &c., inner defences (Inchgarvie, Dalmeny, Carlingnose, and coastguard batteries). Lieutenant R. I. Rowley is posted to the Mandalay District for duty in the Station Hospital, Shwebo. Lieutenant-Colonel W. L. Lane, in medical charge of the Station Hospital at Ahmednagar, and Lieutenant-Colonel G. E. Weston, in medical charge of the Station Hospital at Nusseerabad, hold themselves in readiness to proceed to England. Lieutenant-Colonel F. P. Nichols, doing duty at the Station Hospital, Mandalay, is ordered to assume the medical charge of the Station Hospital, Shwebo, vice Major W. S. Boles, who proceeds to Mandalay. Captain Hall assumes charge of the Station Hospital at Calicut, vice Lieutenant-Colonel J. Maconachie, proceeding to Nusseerabad, in the Bombay Command, for duty.

The Government of India has sanctioned house rent for all officers of the Royal Army Medical Corps of the establishment authorised for employment in Station Hospitals at the Presidency towns of Bombay, Madras, and Calcutta, provided such officers are not supplied with public quarters.

### IMPERIAL YEOMANRY (IN SOUTH AFRICA).

The undermentioned officers having relinquished their commissions are granted honorary rank in the Army as follows, with permission to wear the uniform of the corps:—

*1st Battalion:* Temporary Captain E. T. Shorland, Medical Officer, to be Honorary Captain. Dated April 9th, 1901.

*10th Battalion:* Temporary Captain E. Hopkinson, Medical Officer, to be Honorary Captain. Dated July 18th, 1901.

*12th Battalion:* Temporary Captain H. Manders, Medical Officer, to be Honorary Captain. Dated July 10th, 1901.

*13th Battalion:* Temporary Captain F. A. Hadley, Medical Officer, to be Honorary Captain. Dated June 2nd, 1901.

### VOLUNTEER CORPS.

*Artillery:* 1st Berwick-on-Tweed: Surgeon-Lieutenant C. L. Fraser to be Surgeon-Captain. 1st Midlothian: Surgeon-Lieutenant A. A. S. Skirving, C.M.G., to be Surgeon-Captain. Supernumerary Surgeon-Lieutenant W. M. Taylor to be Surgeon-Lieutenant on the Establishment. 1st Newcastle-on-Tyne; Surgeon-Captain P. H. Watson resigns his commission. *Rifle:* 1st Volunteer Battalion the Cheshire Regiment: Surgeon-Lieutenant A. R. Wilson to be Surgeon-Captain. 1st Volunteer Battalion the Prince of Wales's Volunteers (South Lancashire Regiment): Surgeon-Lieutenant J. N. Patterson to be Surgeon-Captain. 7th (Clackmannan and Kinross) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders); Surgeon-Lieutenant S. Ferguson resigns his commission. 26th Middlesex (Cyclist): Surgeon-Lieutenant P. J. Edmunds to be Surgeon-Captain.

### SOUTH AFRICAN WAR NOTES.

Lieutenant M. F. Foulds, R.A.M.C., recently reported dangerously wounded, has had his right leg amputated at the knee. The injury was received at Harrismith on Dec. 30th.

Civil Surgeons John Collett Osborne, John Wigglesworth, Harold Sidney Callum, and T. Parker have been discharged from hospital to duty.

### NAVAL COURT-MARTIAL AT CHATHAM.

A court-martial was held on Jan. 3rd on board the *Forte*, at Chatham, for the trial of Fleet-Surgeon Robert William Anderson of the *Andromache*, in connexion with the illness and death of a stoker named George Belleney between Nov. 22nd and 25th, 1901. There were two charges: the first alleging negligence and want of due professional care, and the second alleging omission to comply with the regulations ordering the sick to be visited twice daily and oftener if necessary. The court found the charges proved and ordered the accused to be severely reprimanded and dismissed his ship. It appears that the stoker in question was admitted to the sick bay of the *Andromache* at North Shields on Nov. 23rd, with a history that he had been previously suffering for a few days from the symptoms of an ordinary cold. Shortly before his admission he had walked about five miles in the wet and cold. Pneumonia followed and death suddenly and unexpectedly occurred owing to heart failure. Fleet-Surgeon Anderson, who was on short leave at the time but occupying a house in the neighbourhood, was communicated with and saw the deceased, but it does not seem that he or the sick-bay attendant found any cause for apprehension in the patient's condition; indeed, it is stated that his temperature was normal. But the report in the *Times* of the proceedings of the court-martial is not such as to enable us to arrive at any definite opinion, for we are not told whether the patient's temperature remained normal throughout his illness, what was the rate of respiration, or whether the medical examination included any special physical examination of the chest. It seems clear, however, that the serious or urgent nature of the case was not suspected by those in the sick bay or in immediate attendance on the patient, and his illness, therefore, did not attract the attention which it would otherwise have done. Fleet-Surgeon Anderson, it is right to say, had always previously held a high character for his care and attention to the sick. We think that it is to be regretted that he did not proffer himself for examination on oath by the court.

### HEALTH OF THE UNITED STATES NAVY DURING 1900.

The medical report on the state of the United States navy during the year 1900, drawn up by Dr. W. K. Van Reypen, Surgeon-General of the navy, is a voluminous work, including a great many reports presented by individual officers, and in the aggregate filling 328 closely printed pages. The health of the navy and marine corps for the calendar year 1900 was satisfactory. The average strength of the active list was 23,756, an increase of 2937 over the previous year. The total number of admissions to the sick-list for all causes was 18,936; of these, 15,829 were for disease and 3107 for

It is a pity that Mr. Spencer should blame those of his professional brethren who are ambulance lecturers, for he should have sufficient confidence in them to know that they would never teach such glaring mistakes as he mentions, but he should be excused if he blamed the lay public for not paying sufficient attention to the lectures and instruction given them, and also for not keeping up the general principles taught them.

I am a lecturer of 20 years' standing and an examiner for the St. John Ambulance Association, and have probably seen a good deal more of ambulance work done by the lay public than Mr. Spencer has, and am proud to say that I have seen much excellent work done by holders of the First Aid certificate, and have known more than one life saved by their prompt attention. As an examiner I say that I should not hesitate to pluck any candidate who told me that he would act in the way that Mr. Spencer describes. In conclusion I cannot help saying I do not wish to shield those laymen who made the mistakes Mr. Spencer has mentioned, but it is not the fault of the teaching; it is the difficulty of driving plain common-sense into the heads of some people.

I am, Sirs, yours faithfully,
JAMES J. MARSH,
Surgeon to the Belgravia Nursing Division of the
Jan. 6th, 1902. St. John Ambulance Brigade.

---

*To the Editors of* THE LANCET.

SIRS,—As a lecturer on first aid for over 16 years and an examiner for many years I ask you to allow me to reply to a letter by Mr. W. G. Spencer in THE LANCET of Jan. 4th. Mr. Spencer details a list of cases in which improper first aid has been the cause of disastrous results. Of course, good intentions cannot be adduced as an excuse for ignorance or justify doing harm although meaning well. But it is in his deductions that I take exception, as I consider they are formed upon an imperfect basis. He states that because those who have been pupils of ambulance classes have in many instances made grievous errors in first aid treatment, therefore the instruction given has been wrong. He says: "It would appear that instruction is given in such classes which is not informed by the actual requirements of practical surgery. Those who have attended such classes seem to have got the idea fixed in their minds that they must always apply some sort of an improvised tourniquet to the limb above the bleeding point, whilst they have not learned in these classes the necessity of applying pressure directly to the wound."

I have always impressed upon my classes that the two most important things to remember in first aid to a case of hæmorrhage are—position and pressure upon the bleeding point. I have examined classes all over East Kent and I have universally found that the same teaching has been adopted, and it has been a very rare exception to find a candidate applying a tourniquet, except as an adjunct, when the hæmorrhage was arterial and excessive. I will not go further into details, but must say from my experience that the teaching in first aid classes in connexion with the St. John Ambulance Association is sound from a surgical point of view and in no way deserves the public strictures which Mr. Spencer has directed against it.

The practical side of the question raised is of great importance, as such disastrous results of first aid call for a remedy as speedily as possible. This, I believe, can only be achieved by discovering the true cause of the ignorance displayed, and not by hasty condemnation. In my opinion the defect lies in the short course of instruction—viz., five weekly lectures. With enthusiastic pupils, reading up their notes and book, this is sufficient to enable them at the end of the sixth week to pass an examination with about 60 per cent. of marks. But evaporation soon takes place, and unless they continue their reading they soon become very uncertain and mixed in their ideas as to what they should do in any emergency. This is a natural result. Therefore, the remedy appears to be to prolong the course of instruction, and thus give an opportunity of more firmly fixing the principles of first aid on the minds of the pupils. I have had many opportunities of seeing cases in which suffering has been greatly relieved, and in more than one instance life probably saved, by properly applied first aid, and I feel strongly that encouragement ought to be given to every man and every woman to acquire a knowledge of it rather than discouragement.

Defects and ignorance certainly are rightly and justly brought before the profession, but I fail to see any justification for making ruthless accusations against ambulance teachers without any evidence whatever. I maintain that they have not deserved this censure, as they cannot be held responsible for the fault of others.

I am, Sirs, yours faithfully,
Herne Bay, Jan. 6th, 1902. EDWARD C. FENOULHET.

---

*To the Editors of* THE LANCET.

SIRS,—It is with the greatest satisfaction that I see that a surgeon of Mr. W. G. Spencer's position has taken up this important subject, the necessity for reform in which was first forcibly impressed upon me by a case which occurred when I was a house surgeon at St. Bartholomew's Hospital. Although almost exactly similar to one related by Mr. Spencer, yet it is so typical that I would wish to quote it, for it is difficult to effect an alteration in traditional teaching, and I do not think the point can be too much emphasised.

A workman was carried into the hospital with the history that a piece of iron had fallen against his leg, causing it to bleed freely. and that the foreman of the works, having received ambulance instruction, had duly attended to him. The right leg of his trousers was saturated with blood, and his blanched face and anxious, restless expression showed how severe had been the hæmorrhage. Round his leg were loosely wrapped some rags; on tearing these off an actual jet of blood was disclosed issuing from a small wound in a varicose vein. The tip of one finger arrested this at once, and looking up the leg I found a tourniquet of cord and pieces of wood tied firmly round the thigh tight enough to impede all venous return. This was cut away at once, and there was no further trouble with the hæmorrhage, but the man was not well enough to leave the hospital for a week owing to his anæmic state.

Two things seemed clear in the case: firstly, that if no tourniquet had been applied the bleeding would have ceased spontaneously; and secondly, that if it had not been removed the man would have bled to death. He would have been killed by misguided interference, and this case is but one of many. Surely it is wrong to encourage the use of such an uncertain and dangerous appliance. If it is applied tightly enough not to actually increase the hæmorrhage it must cause great pain, and if not soon removed may determine gangrene of the limb, while in the immense majority of cases it is a quite unnecessarily severe measure. We know that hæmorrhage from wounds of even large arteries—and these form but a fraction of the cases dealt with—can be treated successfully by pressure. Mr. Bowlby, writing of his recent experience of cases of primary hæmorrhage in South Africa, states that "in the vast majority of cases rest, pressure, and careful bandaging with elevation of the wounded limb, will suffice." Why, then, should the inexperienced be worried and confused by being told first to distinguish between capillary, venous, and arterial hæmorrhage, and to apply different treatment for each, and a tourniquet in one position or the other for the last two, when one simple method, *pressure at the seat of injury*, is the right treatment for the overwhelming majority of them all, no matter where the wound is situated? And add to this confusion the loss of valuable time in trying to determine the particular kind of bleeding in a given case (when probably all three are occurring) and then improvising and attempting to apply a tourniquet in what is imagined to be the right place. The only objection to local pressure seems to be a possibly increased risk of sepsis from direct applications to the wound, but I cannot think this of much weight practically.

The fact seems to be that the tourniquet idea appeals to the average person and sticks in his mind, although undue stress may not be laid on it in the ambulance books and classes. But it is the object of first-aid instruction to impart something clear, lasting, and, above all things, useful, to the minds of those who attend, and in the subject of the arrest of primary hæmorrhage I think all must agree with Mr. Spencer that this end has not been attained by the methods of teaching at present in vogue.

I am, Sirs, yours faithfully,
R. DE S. STAWELL, M.B. Cantab., F.R.C.S. Eng.
Shrewsbury, Jan. 6th, 1902.

## CARCINOMA AT AN EARLY AGE.

*To the Editors of* THE LANCET.

SIRS,—The following may be of some interest from the early age at which the disease developed. Last week he attended a woman, aged 24 years and five months, in and commerce as a whole would pass into the hands of the State, an alternative which certainly offers one solution of the social problem but which would leave individual initiative out in the cold. I should certainly prefer supervision by the State, but such supervision would require to be exercised by thoroughly competent experts—that is to say, medical men who prepare their own vaccine. In such case would these medical men *qua* manufacturers of vaccine not in all probability *display a tendency to believe that their own methods* are the best and that all other procedures are necessarily inferior to their own? Obviously this suggestion is impracticable. In all establishments, whether public or private, in spite of every possible precaution, there are times and seasons at which the vaccine product is inert or comparatively inactive, the reason of which is still unknown. There are periods, indeed, when this sterility affects whole countries. I am in communication with a large number of *vaccine institutes throughout* Europe *and can speak* with authority on this point. We may therefore take it as proved that at certain times this or that institute will produce only inert lymph. A lymph which was originally very active may become inert in a very short space of time, while other specimens will retain their activity unimpaired for an indefinite period. The accuracy of this observation can be *testified to by all directors of vaccine institutions.* There is a third fact—viz , that lymph too freely diluted with glycerine or water loses its virulence. We are confronted, therefore, with three causes of inert vaccine: (1) defective virulence *ab origine;* (2) spontaneous loss of virulence after a short time; and (3) loss of virulence as the result of too free dilution.

Now for the remedies. *It is indispensable in the first* place that directors of vaccine institutes should test their glycerinated lymph. This test may be applied on the rabbit, the calf, or the child. The only real test is that on the child, because a vaccine which takes very well in the animal may fail in the child. Since vaccine, when first gathered, always contains a large number of micro-organisms, possibly pathogenic, it must be allowed to stand for some time in order to allow of the destruction of the greater part of these organisms. Vaccine a month old and free from injurious organisms must be inoculated by means of incisions of sufficient length and well separated so that the vaccinal vesicles may run a separate course at the site of each incision. The evolution of the vesicle must be inspected daily and it is on the third or fourth day (not the eighth) that one can form an opinion as to the value of the vaccine. If we make an incision one centimetre in length the vesicles at the end of the third day should be present in such abundance as to look like a single vesicle with straight edges following the line of incision. If the margins are irregular or dentated the vaccine is not of the first quality. If along the incision there are only one, two, or three isolated vesicles which do not become confluent for a day or two the vaccine is not active enough for use. When vaccine remains in stock for several months it is the duty of the director to test *it from time to time,* eliminating *on each occasion* all vaccine which shows itself inactive. By following this procedure the institutes will furnish vaccinators only with active lymph which will invariably *give satisfactory results—i e ,* 100 per cent. for vaccinations and 80 per cent at least for revaccinations.

Loss of activity as the result of too free dilution is the least important because it can be made a rule never to mix with the pulp more than the quantity of glycerine absolutely necessary to render it fluid and to allow of its introduction into tubes. *Glycerinated pulp ought always to be thick, and* in no case should the proportion be exceeded of four parts of glycerine to one of pulp gathered by the curette without forceps—that is to say, not already diluted with blood serum. If all vaccine institutes follow the method which I have just described they will never supply vaccinators with inert lymph, though they themselves may now and again find themselves in possession of inert lymph and they may even have a run of bad luck in this direction. What, then, is the remedy? There are several, but I will limit myself to one—viz., never vaccinate the calf with fresh lymph, but use vaccine which has been in stock for two, three, or four *months, the perfect virulence whereof has been ascertained* by previous tests. If, in spite of this precaution, the desired result is not obtained recourse should be had to an institute which is furnishing an active lymph, and a series of calves vaccinated with this lymph after having tried it on a child. No attempt should be made to start the series with lymph of one's own preparation until one is sure that the bad period is at an end. The obligation to have *occasional recourse to* another institute is a strong argument against the proposed State monopoly, because should the State vaccine become inert it would perforce have to find an institute in a position to supply it with active lymph to start afresh with, and if the institutes in Europe were restricted to a few State institutes it might very well happen that they were all *suffering from the same defect* at *the same time.*

What would seem particularly desirable is the establishment of a closer relationship between all vaccine institutes in Europe, or even of the whole world, so that they may come to each other's assistance. I have endeavoured to establish some such intercommunication and I am pleased to say that my appeal has been favourably received by a certain number of *institutes in England, Germany, Austria, Russia, Spain,* Portugal, Switzerland, and France. I hope ultimately to succeed in forming a sort of syndicate of vaccine institutes. When I have attained that object the problem will have found its solution and in the event of a lack of virulence the institutes will know where to put their hands on the supply of active pulp or lymph which they require.

I am, Sirs, yours faithfully,
EDMOND CHAUMIER, M.D. Paris.

# FIRST AID FOR PRIMARY HÆMORRHAGE: THE WRONG TEACHING GIVEN TO AMBULANCE CLASSES.

*To the Editors of* THE LANCET.

SIRS,—I read Mr W. G. Spencer's letter on the wrong teaching given to ambulance classes in THE LANCET of Jan. 4th with surprise. *He seems to take it for granted* that because a person has gone through one course of lectures on "First Aid" and treats a patient wrongly that the lecturer must be at fault, because the said person *says* he was taught to do what he did I am perfectly aware that a deal of harm is done by people who attend one course of lectures and no more and, maybe years after, when suddenly called upon to stop hæmorrhage and having only a hazy recollection of what they ought to do, clap a tourniquet on somewhere or other, and cover their retreat by saying, "That is what I was taught to do." But when you come to a trained body of men, such as the St John Ambulance Brigades, who are constantly rendering first aid under the *immediate supervision* of an honorary surgeon of the brigade, my experience *is totally different.* *I have never* seen a case of primary hæmorrhage that was not treated in the same way as I should have done myself—viz: (1) by digital pressure in the wound; and (2) by a hard pad and bandage (if available) over the wound. If a member of the Worksop Division were to tie a handkerchief "on the side nearest the heart," instead of *directly over* a ruptured varicose vein, I *should advise him to go home,* burn all his certificates. and hand in his resignation.

I am, Sirs, yours faithfully,
A. J. HELM MONTAGUE,
Honorary Surgeon and Superintendent, Worksop Division,
St John Ambulance Brigade.
Jan. 6th, 1902

---

*To the Editors of* THE LANCET.

SIRS,—In answer to Mr. W. G. Spencer's letter on the subject of "*First Aid and Primary Hæmorrhage:* the Wrong Teaching given to Ambulance Classes," I am sorry that he has made use of a wrong statement in the latter part of his heading, because in the commencement of his second paragraph, he says, "It would 'appear' that instruction is given in such classes which is not informed by the actual requirements of practical surgery." By saying this he goes against the *positive* statement given in his heading.

Surely, Sirs, Mr. Spencer cannot for one single moment believe that any qualified medical man (who alone are entitled to lecture and examine for the St. John Ambulance Association) would be foolish and ignorant enough to leave out in his lecture *the first general principle of the arrest of* hæmorrhage? If so, he can have very little faith in his own *cloth.* If Mr. Spencer will look at the "Text-book on First Aid" which is supplied by the St. John Ambulance Association, and on which lecturers have to give instruction, he will find clearly printed and in large type what he says *is* not taught, and it is in such languauge that the most ignorant person who is able to read can easily understand.

lessons which they have received in elementary hygiene, a knowledge which those around them may readily acquire.

It is much to be regretted that many in whom the disease is more firmly established are unable to remain in sanatoriums long enough to enable us to put "arrested" after their names when describing their condition on leaving. When the profession, and perhaps the public as well, realise the vital importance of *early* treatment and patients are sent in before the disease is firmly established; and when slight apical dulness and prolonged expiration are, with the subjective symptoms we all know, regarded as more than suspicious, the numbers who must now be returned to their homes as "not improved" will be very small. In many cases the "treatment" as regards the open window, dietary, and exercise is followed up at home with excellent results.

I venture to think that the term "aggregation" is inapplicable. Flocking together of the patients is very strongly discouraged. There may be two in one shelter or a larger number in a roomy, breezy ward; but here, as in the dining-hall—the only place where patients come together—the air-space is unlimited and the air in motion, and this motion of the air is the very essence of the open-air feature of sanatorium treatment. Closed windows or shelters that do not permit the free passage of air-currents ought never to be used. If the patients were allowed to occupy a still and stagnant atmosphere the *circulus vitiosus* might be created, but under proper sanatorium treatment this could never be the case, the aërial currents removing at once all organic matter and bacilli which are soon destroyed by nature's methods—air and sunlight. In this way no zone of infective matter can be formed and infection is impossible. With a single open window the thorough purification of the air cannot be assured and herein lies the difficulty, or one of them, of carrying out the treatment away from a sanatorium which is literally an open-air institution. Unfortunately, in the vast majority of dwelling-houses the air is vitiated more or less and here infection is very probable, but we do not learn of any attendant on consumptives being attacked, nor are there any grounds for assuming that reinfection does take place. And I doubt if such is possible in a well-constructed and well-conducted institution. The patients themselves enjoy their healthy surroundings and fairly revel in the fresh air, and to one who has lived in a sanatorium no word could seem less suitable than that of "prison" used by Mr. Marriott. The cheerfulness, the ready acquiescence to the necessary discipline, the returning health, the hopefulness of recovering patients and their enjoyment of their surroundings tend to produce a harmony and brightness far from one's idea of durance vile. The disease, we know, is not to be eradicated by sanatorium treatment alone, which deals mainly with a result but in some measure reaches the cause by the dissemination of knowledge of the best means of promoting health and preventing infection. . The patients learn the value of fresh air, instruction in the use of which is needed so urgently amongst all classes, as the poisonous atmosphere of public buildings and conveyances as well as residences amply testifies; so that while all effort should be made to promote a higher standard of health by the adoption of thorough ventilation, better housing of the working-classes, modern drainage systems, and other sanitary measures, no pains should be spared to ameliorate the condition of those who are afflicted.

It does not follow that any claim has been made for a "corner" in fresh air because the treatment cannot always be effectually carried out at home. Though fresh air may be the principal agent in the treatment there are others which are of hardly less importance. I mean a careful regulation of the patient's daily life in every detail, and this, I believe, can, until the patient is in a fair way to recovery or the disease of very early stage, only be carried out in a sanatorium where the patient is guided by those who have made a special study of the disease and are accustomed to sanatorium practice. Under these conditions the happiest results may be looked for in those who come under treatment at an early stage of the disease, and often to those in whom evidence of consolidation of extensive area of lung is not wanting hope of prolonging life under pleasant circumstances may be given.

I would add a word about the condition of the teeth in phthisical patients, a matter on which one can hardly bear too strongly. It is an exception, in my experience, to find even a moderately good set of teeth; not only is the masticating power lost or defective, but the mouth is often filled with stumps in all stages of decay. The food, on which the feeble patient is so dependent, is not only introduced at the very entrance to the digestive tract to the action of septic micro-organisms, but is swallowed in masses too large for the enfeebled digestive organs to deal with. I would make it a rule that prior to the treatment of a consumptive patient the teeth and gums should receive the attention that will enable them to fulfil their important offices effectually.

I am, Sirs, yours faithfully,
W. M. M. JACKSON
(Late Resident Medical Officer, Westmorland Consumption Sanatorium).

*Scarborough, Jan. 4th, 1902.*

## THE LONDON LICENTIATES' AND MEMBERS' SOCIETY.

*To the Editors of* THE LANCET.

SIRS,—I would like to state concerning the paragraph in your annotation of Jan. 4th—

> *If the London Licentiates' and Members' Society can prove that* the diminishing number of medical students at the metropolitan schools is really due, or largely due, to the fact that the title "Dr." is not obtainable through the portals, &c.,

I submit that little further proof is necessary, for it is well known and felt by the teachers of London that the grave disabilities of London medical students have been an ever-increasing cause of dissatisfaction for the last 15 or 20 years and have culminated in many men joining provincial schools. As regards provincial men, it is unlikely that Welsh, Liverpool, and Birmingham students will be induced to come to the metropolis, London offering practically no pass degree as a reward when they have degree-granting bodies of their own. It must also be remembered that the Carnegie Trust of £2 000,000 will naturally act as a further stimulus for Scotchmen to return to study medicine in Scotland. I have been repeatedly informed by conjoint men that they strongly advise intending students to avoid coming to London under present circumstances. I think the above facts go to show that the absence of attraction in London with the counter-attractions elsewhere is, and will be, the further cause of a diminution in the number of London students.

I am, Sirs, yours faithfully,
FREDERICK W. COLLINGWOOD

Wimpole-street, W., Jan. 4th, 1902.

## IRRIGATION IN INFANTILE DIARRHŒA.

*To the Editors of* THE LANCET.

SIRS,—In THE LANCET of Dec. 21st, 1901, p. 1728, Mr. W. B. Bennett reports a case of epidemic diarrhœa in an infant treated by irrigation of the bowel. Only on one occasion was irrigation performed and immediate and lasting relief followed, although on withdrawing the nozzle of the syringe the injection was "immediately shot out in all directions." While agreeing with Mr. Bennett as to the value of this form of treatment, I cannot but think that the evidence adduced in his case is not very convincing It is not easy to persuade oneself that the almost momentary presence of a weak solution of permanganate in the bowel could bring about immediate and lasting cure of a disease which had resisted all other treatment for nine days; at any rate, I fear that anyone expecting a like result would be disappointed in a considerable proportion of cases. If Mr. Bennett had been able to report upon the result of similar treatment in others of the many cases which came under his care last summer it would have been of greater value. My own experience of this treatment has so far been very limited In one case of very obstinate diarrhœa in a child, aged 13 months, treated in the summer of 1900, irrigation was, I believe, the means of saving the child's life. The diarrhœa had persisted for about six weeks before I began to irrigate, from 10 to 25 extremely offensive watery motions being passed in 24 hours, with latterly mucus and streaks of blood, in spite of dieting—whey, albumin water, and raw meat-juice being successively tried, and bismuth, salicylate of soda, resorcin, creasote, tincture of opium, &c., in the way of drugs. I commenced by injecting half a pint of weak boric acid solution twice a day, gradually increasing it, under low pressure (and desisting as soon as the child showed any signs of discomfort), up to nearly two pints. This treatment had, however, to be continued first confinement, but she was unable to nurse the child as one breast was removed in April last for carcinoma and the other now shows some evidence of being implicated. She has been married about 12 months and it is two years since she first noticed a lump in the breast. The diseased tissue was subjected to a pathological examination and the diagnosis was confirmed before operation. Her mother is stated to have died from a "tumour in the side." *There is nothing else of importance in the family history.*

I am, Sirs, yours faithfully,
E. F. O'FERRALL, L.R.C.P. Lond,
Brixton, S.W., Dec. 16th, 1901.

---

# THE SANATORIUM TREATMENT OF CONSUMPTION.

*To the Editors of* THE LANCET.

SIRS,—I noticed with great regret that in THE LANCET of Dec. 28th, 1901, p. 1843, Mr. Edward Dean Marriott used Sir Dyce Duckworth's remarks, on the personal factor in tuberculosis as a text to anathematise the sanatorium treatment of consumption and all who follow it; and I venture to controvert several of his statements, as I feel that his letter, if left unchallenged, might do much to throw discredit upon a *method of treatment* the value of which we in England have but lately recognised. Apart from various side issues which your correspondent raised, such as the question whether tuberculosis is an infectious disease, the main burden of his philippic was grouped under these headings: 1. Is any scheme devisable by means of which the aspirations of the National Association for the Prevention of Consumption and other Forms of Tuberculosis can be attained? 2. Judged by their own theories of disease-causation, does the aggregation of cases of consumption in sanatoriums recommend itself to ordinary common sense? 3. Are these extraordinary efforts being directed in the true spirit of disease prevention?

1. Dealing with the first question Mr. Marriott very rightly lays stress on the fact that in order to effect a permanent cure the treatment taught in *efficient* sanatoriums must be kept up by the individual patients for two or may be three years; but there is nothing to support his *deduction that a patient must spend these two or three* years in a sanatorium. It has been found, after an experience of 10 or more years, by competent authorities such as Brehmer and Otto Walther, that patients can complete their own "cure" in the greater number of instances after they have spent from four to six months in a sanatorium. During these four to six months the greater number lose all the active symptoms of their disease, which assumes a quiescent and fibrotic character, and in addition they learn the infinity of detail which is necessary to their well-being and by following which they can consolidate their "cure." Mr. Marriott is not justified in making his deduction that the time required is so long that "the financial problem alone is absolutely insoluble," for Sir John Burdon Sanderson,[1] in an admirable address on our duty to the consumptive breadwinner, has shown that the financial problem involved has already been solved in Germany by a system of compulsory insurance; in other words, "every workman whose income is less than £100 a year is required by a law, which came into full operation about *10 years ago*, to insure himself against the two greatest ills flesh is heir to—sickness and old age." Part of the funds accumulated in this manner has been devoted to the establishment and upkeep of the numerous sanatoriums which now exist in Germany for the treatment of consumption among the poor.

2. Mr. Marriott asks the question, Does the aggregation of cases of consumption recommend itself to ordinary common sense? and then asserts that the atmosphere of sanatoriums is so laden with tubercle bacilli that it is a positive source of danger to the patients Now, sanatoriums are usually built where sunshine and pure fresh air—the two greatest enemies the tubercle bacillus has—are most abundant and every precaution is taken in efficient establishments of the kind to avoid any possible spread of infection. In fact, it seems highly probable that the "atmosphere" of any good sanatorium is far more free from tubercle bacilli than the "atmosphere" of an ordinary English house. Your correspondent further bolsters up his argument by stating that the aggregation of cases of scarlet fever and diphtheria in isolation hospitals has been followed by nothing but harm and has created a disease—post-scarlatinal diphtheria. If he will put himself in communication with the medical superintendent of some such institution as the London Fever Hospital, where the treatment of these diseases is carried out on rational open-air lines, I think he will find that the complications and sequelæ met with there compare most favourably with those which obtain in ordinary houses.

3 Mr. Marriott holds that he is committing a heresy in saying that consumption is chiefly caused by want of cubic space and by defective drainage. His figures on this point are hardly necessary, for, as Sir John Burdon Sanderson has said, "the prevalence of phthisis is now recognised as one of *the most certain indications of sanitary defects*"; but, notwithstanding his recognition of the fact that absence of fresh air, together with the presence of debilitating influences, such as bad drainage, are the main etiological factors in consumption, your correspondent strongly protests against any endeavour being made, by means of sanatorium treatment, to place those already afflicted with consumption under such conditions that they may have a continuous supply of fresh air together with complete absence of debilitating influences.

To quote Sir John Burdon Sanderson once more, "Sanitary improvement is only one of the lines along which we have to work in the combat with pulmonary tuberculosis. ...... In other words, *sanatoria for the poor are a necessity.* It is 10 years since this great necessity was recognised in Germany. It has not, even yet, been recognised in England." I would add that Mr. Marriott has also failed to recognise the enormous educational value of sanatoriums and of hospitals such as the Brompton Hospital for Consumption.

Your correspondent enters a further "earnest protest" against specialisation in this disease. He says that this is equivalent to making a "corner" in fresh air. As those who have carefully studied efficient sanatorium treatment know, fresh air is one, but *only one, of the essentials of the treatment* and is not the end and beginning of it. Dr. Otto Walther, in a recent letter to me, says, "The importance of 'individual treatment' must be emphasised again and again. There is no rule which has not to be altered more often than followed." So far as my own experience goes I am convinced that the personal factor in tuberculosis receives more anxious attention in efficiently conducted sanatoriums than under any other conditions

If Mr. Marriott is merely inveighing against sanatoriums run on the principles of an hotel and mainly for profit I am entirely with him, but it is unfair to throw discredit upon a vital form of treatment because certain men have succumbed to the "grosser temptations of the hotel-keeper."

I am, Sirs, yours faithfully,
Brook street, W., Dec 30th, 1901. ARTHUR LATHAM.

---

*To the Editors of* THE LANCET.

SIRS,—Mr. E D. Marriott, in his letter in THE LANCET of Dec. 28th, 1901, p 1843, has touched on several points of special interest at a time when the sanatorium or open-air treatment of tuberculosis is occupying the thought and attention of the profession and the public. The cure of phthisis by the open-air treatment has for a long time been a favourite theme of the public press. So radical a change in the principles of treatment as was the exposure of feeble consumptives to the action of cold, fresh air, regardless of climate and season gave rise to amazement, and often to incredulity. From various sources came tales of wonderful "cures," the enthusiasm of the ardent supporters of the treatment and the press notices leading many to expect the impossible. The hope and anticipation of the profession itself have hardly been as yet fully realised, but there is every reason to feel sanguine, looking at the results which have already been obtained. As more data come to hand and those interested in the work have further experience, the subject will be put on a clear and well-defined basis. As regards the use of the word "cured" it is not now generally adopted and it is unlikely that careful men in charge of sanatoriums will use the expression We are justified in substituting "arrest," as those who have had charge of sanatoriums can well testify. Argument on the use of such terms as "cure" and "first stage" case throws no discredit on the treatment. The fact remains that the large majority, if not all, of the *early* phthisical patients are enabled to return to their homes and occupations in robust and vigorous health—a striking object-lesson to all of the value of properly conducted open-air treatment. *Not only* do they carry away with them a healthy frame, but a mind widely expanded by the practical logically refuse by advice of their solicitor by-laws which according to their own statement they do not possess? It was on Feb. 25th of last year when I first applied to the Registrar for the said by-laws.

---

[1] Brit. Med. Jour., July 6th, 1901.

I am, Sirs, yours faithfully,

Dublin, Jan. 8th, 1902. S. WESLEY WILSON.

## MUNICIPAL BACTERIOLOGISTS.

*To the Editors of* THE LANCET.

SIRS,—The annotation headed "Municipal Bacteriologists," which appears on page 47 of THE LANCET of Jan. 4th is scarcely distinguished by your usual accuracy. A complete department of bacteriology has been working in the borough of Camberwell for more than four years, and its foundation was commented on at the time, whilst various features of its working have been noticed since, in your own columns. The example thus set has been fairly widely imitated, and, so far as my information goes, neither Cambridge nor Liverpool can claim anything like priority, even in succession to Camberwell. I am happy to be able to add that not only was the local authority of this borough the first to recognise the value of work in this particular direction, but that there is no suggestion which I have been able to make in connexion with it which has not been promptly adopted and carried out as thoroughly as money and trouble could do it. Honour to whom honour is due.

I am, Sirs, yours faithfully,
EDWARD C. BOUSFIELD,
Bacteriologist to the Metropolitan Borough of Camberwell.
Old Kent road, S.E., Jan. 4th, 1902.

## THE TEACHING OF ANÆSTHETICS.

*To the Editors of* THE LANCET.

SIRS,—In THE LANCET of Dec. 7th, 1901, p. 1638, Dr. Heron Watson is reported to have said, during the discussion of the General Medical Council on the above subject, (1) that the subject was taught in Scotch universities; (2) that nurses and dressers were taught the use of anæsthetics in Scotch hospitals and infirmaries; and (3) that *there were no accidents in the said institutions with anæsthetics.*

Now, while the subject of teaching anæsthetics systematically—i.e., compelling the student to attend a course of instruction and show a certificate of such attendance at his final examination—may be one over which there is room for discussion and diversity of opinion, seeing how overburdened he is with "certificate acquiring" already there can be no good object attained by perversion of the truth, unintentionally or otherwise, and I beg most emphatically to deny the third statement *in toto* and the first two partially. I submit that the teaching of anæsthetics in Scotch universities at the present moment amounts to one lecture given, often perfunctorily, by the professors and lecturers on surgery, some even omitting it altogether. Secondly, *clinically* students from their first year, often totally ignorant of the most elementary physiology, are shown how to give chloroform "by rule of thumb." But I beg to say that nurses are not taught to give anæsthetics. I rejoice to say it. They may have been in Dr. Watson's earlier days, and, indeed, I believe they were. I met one of these said nurses not long since—"one of the old school"—and she gave me a very dramatic account of how a patient died in her hands from $CHCl_3$ once, since when she had refused to touch what was distinctly out of her sphere. In no well-regulated hospital is such a procedure now permitted, and Dr. Watson is hardly doing justice to the school he represents in making such a statement. Thirdly, accidents do occur in Scotch hospitals and infirmaries just as they are known to occur in English hospitals and, indeed, in private practice; of this I have abundant documentary evidence and personal knowledge. In Glasgow during a recent year *50 deaths were registered as due to anæsthetics. In five months 10 occurred in hospitals alone.* These last figures are from the gentleman who conducted the post-mortem examinations on behalf of the Crown. As to Edinburgh I know little except that during the past year there have not been less than six deaths in public institutions. Of Aberdeen I can say nothing, but proportionate results are probable. I need not take up your space with further figures; that these accidents do occur is well known even by the laity through the public press. It is no use moralising on the subject, some of them are quite unavoidable, but it were well if more surgeons had the honesty and common sense of Sir William M. Banks and gave their conclusions and experience to the profession as he has recently done.[1] What is wanted is for practical surgeons in large hospital and private practice to discuss such a matter. I know for a fact that a large proportion of students desire more teaching and more light on various points in anæsthesia. If 90 per cent. of students in our schools were asked why the pupil dilated early in chloroform anæsthesia, why it contracted later, and why if the drug was again pushed it dilated again and remained fixed, not one would reply that the first was due to stimulation of the sympathetic, the second to stimulation of the third nerve or its cerebral centre, and the last to absolute poisoning and paralysis of the third nerve and centre.

Dr. Heron Watson has earned the respect of the whole profession by his versatility and his brilliant contributions to the surgical art, but a man in his position when pronouncing on so important a question should make himself more sure of his facts. Borbonius said:—

> "Tempora mutantur, nos et mutamur in illis."

The latter is not always true. I inclose my card and apologise for the length of my protest.

I am, Sirs, yours faithfully,

Jan. 7th, 1902. NICOL JARVIE.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Plague Epidemic.—The Shortcomings of Indian Municipalities.—Typhoid Fever amongst the Natives.—Confused Terms for Mild Cases of Plague.*

LAST week's figures showed only a temporary diminution in the mortality from plague. This week they have again risen and the total deaths for the whole of India number 8878. The Bombay Presidency returns higher figures—viz., 5989, as against 5655 last week. The Punjab had 1689 deaths, as compared with 1646. There has been an increase in Bengal from 168 to 205. The total mortality in India from plague last year during the corresponding week was 1989 only. Plague seems to be increasing again in Bombay city. In Calcutta also, though the figures are small, there are signs of a recrudescence. The deaths from plague last week were only 21, while for this week 31 deaths are recorded. In Bangalore city and in the cantonment, and also in Mysore city, the deaths from plague are higher.

Notwithstanding the increase of plague in nearly all of the infected districts it is disappointing to find that only 1218 doses of the plague vaccine were sent out from the laboratory at Bombay. Inoculation is being carried on to a limited extent in Poona It is reported that the mortality amongst those recently inoculated is much less than amongst those who were inoculated in 1897. The development of the disease in the district of Lahore and its spread in the Punjab has awakened the citizens of Lahore to take steps against it. A non-official committee has been formed and the station has been divided up into specified areas. The formation of these committees is useful as an instructional movement in sanitation, but their value in controlling the extension of the outbreak is very doubtful. The continued existence of plague has directed more attention to sanitary matters than has been given to them before, so that at probably every infected station in India out of evil will come some good. Some of the municipalities are very apathetic. At Madura, the second town in the Madras Presidency, sanitation is the most crying want. The water-supply is reported as deficient in the hot months. There is no drainage system. There is not a single cart maintained for sewage. The markets are in bad repair and dirty. The night-soil depôt is half under water during the rains and the slaughter-houses are mere inclosures without the barest essentials. The public roads, streets, and lanes are used as latrines. Again, it is reported for the town of Dindigul that the disposal of the rubbish and the night-soil is unsystematically carried out and that the market and slaughter-houses are badly in need of improvement.

---

[1] THE LANCET, Nov. 16th, 1901, p. 1323.

or nearly three weeks before the motions became normal, nd had to be resorted to some weeks later when a relapse ollowed a perhaps too sudden increase of diet, and was then gain successful. In addition to the cleansing of the bowel, robably some benefit is derived from the absorption of fluid f the injection is retained for a sufficient length of time, and or this reason, as well as for the more thorough washing out of he bowel, it is well to use as large a quantity of fluid as can be orne without discomfort and to retain it as long as possible. hough irrigation is a well-recognised form of treatment, it s probably not made use of as frequently as it might be, nd considering the heavy mortality from diarrhœa in nfants any treatment which holds out any prospect of relief s of vital importance. I am, Sirs, yours faithfully,

WILLIAM THORNELY, M B. Cantab.

Herne-hill, S E, Jan. 4th, 1902

## THE CONSULTANT AND THE GENERAL PRACTITIONER.

*To the Editors of* THE LANCET.

SIRS,—The letter of Mr. F. Montague Miller and your leading article on the Relationship of the Consultant and he General Practitioner will do more for the latter in a few months than all the muddling and bungling of the General Medical Council will do for him in a dozen years. I have been engaged in practice for over 20 years, and I have for ome time been very sure that the relationship of the conultant and general practitioner has been steadily altering—or the worse. One reason is, that the general practitioner s becoming more and more of a "general specialist" He as to have nowadays an intimate knowledge of all "special" rgans; firstly, for purposes of passing examinations; and secondly, for the purposes of existing amidst the competition f his fellows. On the other hand, the consultant is rapidly becoming more of a general practitioner. If a specialist he oes not disdain to prescribe for ailments outside his peciality.

Personally, I regret to have to say that although I have eceived every courtesy from some consultants, by the majority I have actually had patients filched It may possibly be charitably supposed that in the bustle of his busy onsulting-room the consultant may "forget" to ask a patient who has obviously been previously receiving treatment from someone (sometimes prolonged) who the somene was, but it certainly is annoying to find that when, having answered a patient's offhand question, such as: "Who is a good man for the toe-nail, doctor?" the patient hereafter goes to the good man "on his own" and never eturns. More than once the explanation has been: "Well, doctor, you see I found him in the end just as cheap as you. He charged me a *guinea*, but as I *told him* I *could not pay* that every time he told me he would see me twice or three times after each fee for nothing; and occasionally he even saw me at the hospital."

No wonder the general practitioner is beginning to fight shy of his consulting *confrère* when the consultant—so-called—salves his conscience forsooth and acts perfectly uprightly by the terms: one consultation one guinea; second ditto, gratuitous; third ditto, gratuitous. Of course he cannot accept a lower fee than one guinea, and equally, of course this is not the same as 7*s*. per consultation. Oh, dear, no! So he retains, if possible, every fish in his net that swims his way, and the general practitioner, finding that such is the case, keeps them in his own pond if possible.

I am, Sirs, yours faithfully,

Jan. 6th, 1902. A GENERAL PRACTITIONER.

## THE LIVERPOOL PATHOLOGICAL DIAGNOSIS SOCIETY.

*To the Editors of* THE LANCET.

SIRS,—In the Thompson-Yates Laboratory Reports, vol. iii., part 1, I find the following facts about the above society. The annual subscription is 10*s* 6*d*., and for this amount any practitioner can send for examination any number of specimens from cases of infective diseases, or tumours, or samples of urine There are 200 members and nearly 1000 examinations were made during the year. This works out at 2*s*. 1*d* for each examination. These facts show that the practitioners of Liverpool, who, I suppose, value the opinion of a consulting physician or surgeon at the usual amount, think that the opinion of a pathologist is only worth 2*s*. What would be the result if the chemical department of a college undertook to carry out the work of consulting analytical chemists for a twentieth of the usual fees? Would not the chemists throughout the kingdom unite in condemning such a practice? I fail to see the difference in principle between such a society as this and a consultative institute for providing cheap medical and surgical consultations, and we know the opinion of the profession with regard to the latter. *Pathologists are necessarily consultants and should* be treated as such.

It is much to be regretted that the Liverpool laboratories, from which such excellent work emanates, should be associated with this society, but Liverpool is not the only defaulter in this respect. There are numerous centres throughout the kingdom at which pathological opinions can be obtained at cheap rates without any questions being asked about the position of the patient in whose favour the opinion is desired, and it is certainly not to the credit of the profession that these societies should continue to exist unless they are restricted in some way or other.

I am, Sirs, yours faithfully,

Leeds, Dec. 10th, 1901 C. POWELL WHITE.

## A SPEEDY METHOD OF RELIEVING THE PAIN OF PILES.

*To the Editors of* THE LANCET.

SIRS,—The composition of the substance referred to at p. 25 of THE LANCET of Jan 4th which gave almost immediate relief to the pain of a protruded pile was 10 per cent of cocaine and 20 per cent. of menthol in oil of theobroma. The reporter probably mistook "p.c." for "c.c." and wrote "cubic centimetres" instead of *per cent.*

I am, Sirs, yours faithfully,

Liverpool, Jan. 5th, 1902. WILLIAM CARTER.

## X RAYS IN THE TREATMENT OF PHTHISIS.

*To the Editors of* THE LANCET.

SIRS,—As an aid to the methods usually employed at the present time in the treatment of phthisis I have used the Roentgen rays. The cases most suitable for this treatment are of course those in which the apex of one lung only is affected. Using a coil giving a 10-inch spark the resulting x rays were focussed on the seat of the pulmonary lesion for an hour or longer each morning and evening. I should be glad if any other practitioners who have used this method would record their experience

*I am, Sirs, yours faithfully,*

Sheffield, Dec. 30th, 1901. E. B. HAZLETON, M.D. R.U.I.

## A DANGEROUS PRINCIPLE.

*To the Editors of* THE LANCET.

SIRS,—In THE LANCET of Dec. 21st, 1901, p 1764, you were good enough to publish under the above heading a letter of mine in reference to the President, Vice-President, and Council of the Royal College of Surgeons in Ireland refusing to give me a copy of their by-laws "by advice of their solicitor" As your readers may recollect, I stated that I asked for these in order to ascertain if they in any way bore upon the following provision of the College charters of 1844 and 1885:—

> And the examiners or any number of them declared by the by law to be competent to transact business as a Court of Examiners shall in the presence of the President or in his absence of the Vice-President and two or more members of the Council examine . ... any candidate for a Fellowship.

Since then a Fellow of the College applied for a copy of the by-laws and received the following reply, under date Jan. 2nd, 1902:—

> SIR,—In reply to *yours of 27th inst. I am directed by the President* and Council to inform you that there are no copies of the by-laws available
>
> A new edition is being prepared, but it will take some time to bring out this edition *as several changes are contemplated in the by-laws* and *Charters*
>
> Yours truly,
>
> JOHN BARTON, F.R.C.S., Secretary of Council.

I admit I am now mystified by the action of the College, for how can the President, Vice-President, and Council administrative block, with which they are connected by corridors, the latter taken together being several miles in length. There are two wings, for the male and female patients respectively, and at some distance away is a hospital for infectious diseases. At the opposite side is a row of houses for officers. On Jan. 6th 25 patients were admitted to the asylum and these will be increased week by week. The asylum will be chiefly utilised for chronic cases. A church is also in course of erection to seat 800 people. There is also a large recreation hall which will accommodate an enormous number. The whole of the buildings were inspected with great interest by the members of the board who expressed the opinion that they would greatly relieve the pressure to which the board has been put to meet the large demands for accommodation for lunacy cases from various parts of the county.

Dr. Gemmel, senior assistant medical officer of Prestwich Asylum, has been appointed medical superintendent of Whittingham Asylum.

### *Bequests to Liverpool Hospitals.*

The late Mr. Alexander Taylor Riddock of Bootle has bequeathed £500 to the David Lewis Northern Hospital and £500 to the Bootle Borough Hospital.

### *The Health Committee and Preservatives and Colouring Matters in Foods.*

The report of the Departmental Committee nominated by the President of the Local Government Board to inquire into the matter of food adulteration and preservatives was the subject of discussion at the last meeting of the health committee. The defence put forward from time to time in the Liverpool police-courts has been that the preservative has certain medicinal merits, and medical evidence has even been adduced in support of this contention, apparently to show that the consumer would derive some advantage from the casual and surreptitious administration of a dose of drugs with his food. Evidence of such a character, the medical officer of health (Dr. E W. Hope) stated, had frequently been given for the defence when prosecutions had arisen on account of the excessive use of salicylates in foods. Dr. Hope pointed out to the health committee that the final recommendations of the Departmental Committee might be summarised as follows. That the use of formalin or formaldehyde should be absolutely prohibited and that salicylic acid should not be used in a greater proportion than one grain per pint in liquid food and one grain per pound in solid food, and that in all cases its presence should be declared; that the use of any preservative or colouring matter in milk ought to be constituted an offence under the Sale of Food and Drugs Act; that the only preservative to be allowed in cream should be boric acid or borax, in amount not exceeding one-quarter of a grain per cent. expressed as boric acid, the amount to be notified by a label upon the vessel; the only preservative to be used in butter and margarine to be the same as in the preceding, in proportions not exceeding half a grain per cent; that in the case of dietetic preparations intended for the use of infants or invalids chemical preservatives of all kinds should be prohibited; and that the use of copper-salts in the so-called "greening" of preserved foods should be prohibited. It was also recommended that means should be provided for more direct supervision over the use of preservatives and colouring matters in foods. Dr. Hope remarked with satisfaction that the report of the Departmental Committee not only confirmed the equity of the action taken by the health committee, but that, if acted upon by manufacturers and dealers, it would remove altogether the necessity for legal proceedings.

### *The Liverpool School of Tropical Medicine.*

The Liverpool School of Tropical Medicine has received the gratifying intelligence that, following up the excellent work done at the instance of the school at Sierra Leone in the direction of destroying the breeding-places of the anopheles mosquito, the Government has decided to adopt similar measures in other West African colonies. In Gambia a special officer has been appointed who is to see that the most stringent precautions are taken in the matter.

Jan. 7th.

---

DIPHTHERIA ANTITOXIN.—At the meeting of the Bridgend Board of Guardians held on Dec. 28th, 1901, it was decided to allow the cost of antitoxin to the district medical officers who used it in cases of diphtheria.

---

## WALES AND WESTERN COUNTIES

(FROM OUR OWN CORRESPONDENTS.)

### *Cardiff Workhouse.*

AN inquest was held at the end of November, 1901, upon the body of a child, 15 months old, who had been taken by the mother from the Cardiff Workhouse on the previous day and who was found to be suffering from broncho-pneumonia and to have a fractured arm which it was alleged had not been diagnosed by the medical officers of the workhouse. An inquiry was held into the circumstances on Dec. 17th by the workhouse visiting committee of the board of guardians, when it was stated that the mother persisted in removing the child in spite of the remonstrances of the workhouse matron who pointed out the serious condition of the patient and that the child was undoubtedly of rickety constitution. A great deal of contradictory evidence was given as to whether the woman who had charge of the nursery, and who was not a trained nurse, did or did not call the attention at various times of the visiting medical officer and of the resident medical officer to the child, and the assistant porter admitted that he forgot to enter the child's name in the medical attendance book on the day before the patient left the workhouse. Both these subordinate officers have been called upon to resign, and at the meeting of the board of guardians on Jan. 4th a resolution was passed declaring that although the evidence at the inquiry did not point to any specific neglect on the part of the medical officers they were deserving of blame for not discovering the fracture. The only comment which it is necessary to make upon this resolution is that the resident medical officer was expected to act also as dispenser and that there are over 1000 inmates in the Cardiff Workhouse.

### *Somerset Lunatic Asylums.*

There are in the county of Somerset two lunatic asylums—one at Wells, established in 1848, with accommodation for 850 patients, and the other at Cotford near Taunton, established in 1897, with administrative accommodation for 700 patients but actual ward accommodation for only 450. At the end of last year there were 850 patients at Wells and 476 at Cotford, a total of 1326, of whom 567 were men and 759 were women. The necessity for completing the ward accommodation at Cotford is therefore very urgent. The population of the county at the last census was about half a million. At a meeting of the county council held on Dec. 31st there was a discussion upon the question of providing a separate institution for the idiot paupers of the county. The asylums committee reported that in the present state of the law county councils were only authorised to provide asylum accommodation for certified lunatics and had no power to provide for the idiots and imbeciles at present maintained in workhouses or boarded out with relatives and friends and not so certified. Sir Edward Fry traversed this opinion, and upon his suggestion a special committee was formed to take the matter in hand

### *Brentry Homes for Inebriates.*

There were at the end of last year 36 men and 170 women under treatment in the Brentry homes for inebriates.

### *The late Mr. F. G. Engelbach.*

At Moretonhampstead parish church on Jan. 1st, in the presence of a large congregation, a memorial tablet was unveiled in memory of the late Frederick George Engelbach, L R C.P. Lond, M R C.S. Eng. The rector (the Rev. S. D Dewey) in the sermon spoke of the formation of the Moretonhampstead Volunteer Corps by the deceased, the great interest he took in it, and his subsequently proceeding to the war and his lamented death there while succouring the wounded. The tablet is of brass on a black marble base and bears the following inscription: "To the glory of God and in memory of Frederick George Engelbach, for 10 years medical practitioner in this town and first commanding officer of the G Company (Moretonhampstead), 5th V.B D B, who was killed whilst succouring the wounded at the battle of Nooitgedacht. South Africa, December 13th, 1900. Erected by the inhabitants and other friends —December, 1901."

Jan. th.

The more frequent reports of cases of typhoid fever mongst natives show that this disease has been hitherto verlooked. Instances of continued fever not due to malaria equire more careful investigation. The intestinal symptoms eem less marked in the native. There may be little or no iarrhœa and not even any marked meteorism. Spots may e difficult of detection and the spleen may have been preiously enlarged. Typhoid fever in the native is more of a ystemic infection without local manifestations.

The case of suspected plague found in West London and eported in THE LANCET of Nov. 23rd, p 1443, is described y Mr. A Baldwin and also by a writer in one of your *ontemporaries* as one of pestis minor notwithstanding that "the bacteriological investigations negatived the idea of the ase being true plague." There is apparently great confusion f terms concerning mild cases of plague and doubtful forms f glandular enlargement. Pestis minor is plague. It cannot e applied to "a specific form of glandular enlargement vhich occurs when plague either threatens or is actually bout" and at the same time not be a mild case of plague t is plague, but a mild form of it, and pestis ambulans is nly another gradation of it. Medical officers in India are amiliar with these cases, but though they may be given lifferent names they are all recognised as cases of plague Surely the proper term for cases not in any way due to lague is "glandular fever." The confusion of terms has risen in England; it does not exist here.

Dec. 15th, 1901.

### *he Plague Epidemic: Prospects in Calcutta and Bombay.—The Distribution of Plague Vaccine—Increase of the Indian Nursing Service.*

THE returns of deaths from plague throughout India luctuate week by week. For the past seven days 7797 leaths have been reported, as compared with 8873 for the revious week. For the corresponding week of last year here were only 2107 deaths While diminishing in some of he places now long infected it is increasing in others. In he North-West Provinces the deaths have risen suddenly in umber from 68 to 228 Plague has appeared in the cities of Kasur and Phillour in the Punjab. There is a slight decline in Bombay city and the number of deaths in Calcutta continues bout the same. In the latter city there is an exceptionally ow general mortality; this is accounted for partly by the few leaths from cholera and small-pox. The infantile mortality s enormous. This low mortality in Calcutta, as compared vith that of the last two or three years, may possibly indicate ither that a recrudescence of the plague outbreak will be leferred or that it will be lessened. The general mortality in Bombay city, also, though high, is below the mean of the corresponding periods of the past few years. The same indication may, perhaps, be seen in the case of Bombay. It is at all events reassuring that the deaths from plague during the past six months favourably compare with the returns of the past two years. There is at present no indication of a recrudescence in Bengal. The disease is declining in Karachi, but it continues virulent in Bangalore city, in the Cantonment, and in Mysore.

The number of doses of plague vaccine sent out from Bombay during the week ending Dec. 13th, 1901, was 7126 As these are less than the number of deaths from plague the progress of protective inoculation can hardly be considered satisfactory. Very little is done in Bengal, and I understand that no operation has been done in Calcutta for some time

It is reported that the Indian Army Nursing Service is to be augmented by seven senior nursing sisters and 32 nursing sisters

Dr. Sarat K Mullick, who in England during the past summer strongly advocated the claims of native medical men to certain posts in India, has returned to India and has been lecturing, amongst other places, in Mysore. He has certainly given good advice to young Indians in urging them to travel and to see England. He tells them that it is quite possible for them to live as vegetarians and total abstainers.

Dec. 20th, 1901.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

### *Hospital Festivities*

CHRISTMAS-TIME has been kept with enthusiasm at most of the hospitals in Birmingham. The authorities of the General Hospital always make every effort to promote the comfort and happiness of the patients This year an entertainment was given by the resident officers on one evening, and on another a similar gathering was promoted by the resident nursing staff. Both were appreciated highly by crowded audiences At the Queen's Hospital the occasion was marked by the richness and variety of the decorations, coupled with the distribution of useful gifts to the patients, ornament and utility being happily combined. The workhouse infirmary, the Eye Hospital, the Royal Orthopædic Hospital, and other kindred institutions provided ample enjoyment for the inmates. At the Ear and Throat Hospital the festivities were damped somewhat by one of the patients committing suicide on Christmas Day by throwing herself over the staircase railing and falling some 25 feet while in a fit of temporary insanity.

### *Milk-blended Butter.*

It would be satisfactory to have some definite legal pronouncement on this subject for the guidance of those who have to investigate the numerous cases constantly occurring at the police-courts. A large firm makes what is called a milk-blended brand of butter, the result being that a large percentage of water is incorporated in it. This compound is sold with a label stating what it is and that it retains about 24 per cent of moisture Two specimens lately obtained for the purpose of prosecution at the Aston Police-court were alleged to contain 26 83 per cent. of water. The Bench dismissed the case The question is one of considerable importance to the dairy trade and is of equal moment to the customers.

### *Middlemore Post-graduate Lectures.*

The annual lecture under this endowment was given at the Birmingham and Midland Eye Hospital on Dec. 19th, 1901, by Mr H Eales, who took for his subject Some Functional Disorders of Vision. A rather small audience listened attentively to the results of the varied experience of Mr. Eales, which he placed before them in an interesting and able manner

### *The Police and the Public.*

At the recent discreditable riots which occurred in this city on Dec. 18th, 1901, a young man met with his death in the street after the meeting had been held at the town-hall. It is alleged that the police, receiving an order to charge the crowd, violently assaulted numerous unoffending persons and that the deceased was struck by a police-officer and knocked down. At the inquest held on Dec. 23rd the medical evidence showed that there was a cut on the right side of the head, the subsequent post-mortem examination revealing a fracture of the base of the skull with rupture of an artery causing effusion of blood. There was much evidence adduced to indicate that the deceased was struck by a baton used by the police The identity of the constable has not so far been established Meanwhile the watch committee has asked for an inquiry by the Home Secretary, which it is to be hoped will be granted

Jan 8th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### *The new County Asylum at Winwick.*

ON Jan 2nd the new asylum at Winwick was informally opened by the members of the asylums board of the county of Lancaster. There was a large attendance The undertaking is an enormous one and has been in progress since 1896 The site was formerly Winwick Park, the residence of the late Canon Hopwood, the vicar of Winwick, and was purchased from the Ecclesiastical Commissioners in 1894 for £21,000 Brick-making was commenced in 1896 and in October, 1897, Messrs. Neill and Company of Manchester signed the contract for the building of the asylum for £253,000 Owing to strikes the work has been delayed on several occasions, but everything will be completed within a few months The buildings will accommodate 1000 male and 1000 female patients and a staff of 200 persons. The block of buildings presents the appearance of a small town, and occupies almost the whole of the large park. The administrative block is in the centre and the remainder of the buildings are built on the pavilion system all around the

Irish Channel, not personally conducted, but with the easterly wind blowing from England—a wind that all good Irishmen have reason to dislike. There are now 39 cases of diphtheria under treatment in the Cork-street Fever Hospital. As to small-pox, a disease which has never been stamped out in the British Isles, one of the most important recommendations of the Cadogan Commission which was appointed to inquire into the causes of the exceptionally high death-rate of Dublin and to suggest means of lowering it was that a hospital should be built outside the city boundary for the isolation and treatment of small-pox. No such hospital has been provided. On Dec. 18th, 1901, 546 cases are reported to have been under treatment in the London hospitals. If the disease comes here, and if its victims are housed inside Dublin, it seems probable that the citizens will suffer and practically certain that the inhabitants of the particular area in which the patients are treated will suffer. Many experiments have been tried with that disease in Dublin, and we now have reason to know its striking distance only too well. In the meanwhile nothing is being done to give it when it does come a wider berth.

### *Royal Victoria Eye and Ear Hospital, Dublin.*

The new buildings in connexion with the Royal Victoria Eye and Ear Hospital have now been commenced in Adelaide-road, Dublin. It will be remembered that about four years ago an Act of Parliament was passed by which the two ophthalmic hospitals of Dublin were amalgamated and their funds united—St. Mark's Ophthalmic Hospital, Lincoln-place, which was founded in 1844, and the National Eye and Ear Infirmary, Molesworth-street, which was established in 1814. Since the amalgamation of the hospitals the joint council thus formed has purchased a site in Adelaide-road free of rent for ever and has, as stated above, commenced the erection of a portion of the extensive buildings required.

### *City Hospital for Diseases of the Skin, Dublin.*

Many patients in this hospital suffering from lupus and allied affections are at present being submitted to the Finsen light cure. The managing committee reports that it cannot extend this system of treatment to numerous applicants seeking admission until it is in command of larger funds. The Right Hon. T. C. Harrington, M.P., Lord Mayor of Dublin, and Sir Charles Cameron, C.B., are honorary treasurers to the fund, to which there have already been many subscribers.

### *The William Smyth Memorial Fund.*

The Belfast contributions to the above fund amount to over £1100, and this sum when added to the £3000 collected elsewhere will, when invested, afford a small return annually until the children of the deceased practitioner have attained ages when they can make some monetary contributions themselves to their mother. It is satisfactory to note that the Right Hon. A. J. Balfour, M.P., has procured a grant of £200 from the Royal Bounty Fund in aid of the fund.

### *Christmas at the Belfast Hospitals.*

At the various hospitals in Belfast the patients were entertained in the usual way at Christmas. There was an immense number of visitors at the Belfast Hospital for Sick Children on Dec. 27th, when the Marchioness of Dufferin and Ava, in the surgical ward, and Lady Dixon (the Lady Mayoress) in the medical ward, distributed the gifts from the Christmas-trees which were provided by friends of the institution for the children.

### *New Technical College for Belfast.*

The City Corporation of Belfast on Dec. 30th, 1901, adopted the plans for the new technical college for Belfast and authorised an application to be made to the Local Government Board for Ireland for its sanction of a loan of £85,000 to carry out the work.

### *The Visit of the King and Queen to Ireland.*

The Lord Mayor of Belfast having written to the Lord Lieutenant of Ireland in reference to the proposed visit of the King and Queen to Belfast, the object being to lay the foundation-stone of the new Royal Victoria Hospital (to be erected as a Jubilee memorial of the late Queen Victoria), a reply has been received that nothing has been so far arranged and that all the rumours are conjectures without any foundation. It is felt in Belfast that in order that due and fitting arrangements should be made for the royal visit sufficient and lengthened notice should be given by the authorities beforehand.

### *The Nursing Question in the Armagh Union.*

The point at issue as to whether or not the Armagh guardians should appoint as an assistant in the infirmary a trained nurse or a probationer (the guardians were prepared to appoint the latter, but to this the Local Government Board for Ireland would not consent) has been settled by the guardians informing the Local Government Board that they were at length prepared to appoint a qualified nurse and one wardsman upon the Board undertaking to withdraw its sealed order calling upon them forthwith to appoint a qualified assistant nurse and three wardsmaids to assist in the infirmary and fever hospital. The guardians on Dec. 31st, 1901, appointed a fully-trained nurse in the fever hospital.

### *Health of Belfast.*

At a meeting of the Belfast City Council on Jan 1st, it was reported that there was a great decrease in the number of cases of typhoid fever. The death-rate per 1000 from all causes during the past year was 21·9, while the average for the previous 10 years was 24·8. There are also a decrease in diseases of the chest and a diminution in the death-rate from zymotic diseases.

### *Rainfall in the North of Ireland in 1901.*

The year just gone has been on the whole for the north of Ireland a fine one, the total rainfall being 39 15 inches (the smallest amount since 1893). The dryness of May and July was noticeable, but the last three months of the year (October, 4·73 inches; November, 4·11; and December, 4 69) converted by a total fall of 13·53 inches what might have turned out an exceptionally dry year into a normal one.

### *Royal Victoria Hospital, Belfast.*

Sir Donald Currie has given £1000 towards the endowment fund of this hospital. Of the £100,000 guaranteed for the building fund £92,589 have been paid, and over £7000 have accrued in interest on the money deposited in the bank.

Jan. 9th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *Dr. Doyen and the Microbe of Cancer.*

The Academy of Medicine has been considering recently a paper laid before it by Dr. Doyen, in which that eminent surgeon announces the constant presence of a new microbe in cancerous tumours—a microbe which after a patient research of 14 years he has been able to isolate and to cultivate. The discovery of the pathogenic microbe of cancer has been often announced before; but Dr. Doyen has not taken the risk of his statement without being sure of his ground and has in no way lightly wagered his reputation. The microbe appears in the form of motile diplococci, one coccus of which is sometimes four or five times as big as the other. Dr. Doyen has managed to cultivate these cocci in tubes of gelatin and of gelose, with the addition of a special nutritive bouillon. Two specimens of cancerous tumour taken from very different organs gave out of 250 tubes inoculated 50 positive results—i.e., 50 pure cultures of diplococci. The growth appeared as a rule within from 24 to 48 hours, but sometimes not until four or five days had elapsed. Besides the diplococcal form the microbe appeared in the form of short chains which sometimes grew in the shape of a Y. On gelose the microbe appeared as a whitish-grey growth, which when taken up by the platinum needle went into thick viscous filaments. In sections of the growth the microbe was difficult to find. It was more easily found in the affected glands and in those secondary growths which were furthest from the original growth. It is found in the blood in exceptional cases of cancerous fever, and in lymphangitis due to cases of pseudo-erysipelatous cancer. Dr. Doyen found the microbe in great purity in a secondary tumour of the pericranium which appeared two years after the removal of a cancer of the breast, in which case there was no local recurrence. It was also found in a serous discharge from the nipple of a woman who had no tumour of the breast, but who was

### *Small-pox in Glasgow.*

THE epidemic of small-pox which has again broken out in Glasgow shows an unfortunate tendency to increase Six new cases were reported at the end of last week and four additional ones have been notified since, making a total of 31 patients in hospital. All the cases except three have come from the same common lodging-house. It is significant that both the lodging-house keeper, who is an anti-vaccinationist, and his wife are among the victims. One of the lodgers, it has been ascertained, had been ill with the disease for nearly four weeks before the nature of his illness was recognised, and it is to this source that most of the present cases owe their origin. Dr. A. K. Chalmers has issued a circular letter to the superintendents of various lodging-houses in the city pointing out the necessity of obtaining revaccination for all the warders, bed-makers, and other servants, and the importance of securing medical advice in any cases of skin eruption among the inmates. In a recent speech the Lord Provost, in dealing with the epidemic of 12 months ago, pointed out the comparatively light and trifling nature of the outbreak and expressed the indebtedness of the authorities to the medical men and the medical students of the city for their cordial cooperation and assistance

### *Glasgow University.*

The register of the General Council of this University for the year 1902 has just been issued. It contains the names of 6031 members, being an increase of 204 on the previous year. The increase raises the quorum required for special meetings of the council from 60 to 72.—The total number of students matriculated at the University for the year 1901 was 1672, exclusive of women students who numbered 352—The Finance Committee of the corporation has again recommended that a sum of £5000 should be presented as a donation to the University. When the former report to this effect was presented to the town council it was sent back for further consideration. The committee has now, therefore, reaffirmed its decision

### *Glasgow Hospitals.*

The active discussion among the staffs of the three general hospitals in Glasgow in reference to the proposal to establish at each hospital an advisory committee consisting of the members of each staff, led some weeks ago to the summoning of a meeting at which all the hospitals were represented Though the proposal met with general acceptance the meeting failed to formulate a detailed scheme for presentation to the various governing bodies, and it seemed probable that the matter would thus be allowed to pass into abeyance. So far as the Western Infirmary is concerned, however, this anticipation has proved to be inaccurate. At a recent meeting of the Board of Managers of the infirmary it was resolved that the senior staff, consisting of the visiting physicians and visiting surgeons, the two physicians for diseases of women, and the pathologist, should be constituted an advisory committee for the current year, in order that the board may obtain its opinion on matters which may arise from time to time and be referred to it by the board for consideration and report. This is so far satisfactory, seeing that it will secure an official statement of the views of the staff on important professional questions arising in connexion with the management of the hospital The recently instituted department for the treatment of lupus, &c., at the Western Infirmary is exciting a considerable measure of interest and is attracting patients from various parts of the country. The infirmary possesses favourable opportunities for securing continuous observation of the effects of the treatment as it has two wards for the reception of cases of skin disease —The usual annual meeting of the nurses of the Royal Infirmary took place in the hall of the dispensary on Jan 1st Addresses were delivered by the Lord Provost and by Mr. J. D. Hedderwick. The latter made special reference to the two new operating theatres which are in course of erection and to the donations which had been received through Dr. M'Intyre for the building and equipment of an electricity pavilion.—On Jan 1st also the annual meeting of the nurses of the Victoria Infirmary took place in the board-room of the institution. Mr. John Paterson reviewed the progress of the infirmary since its foundation and made appreciative reference to the work of Dr. A. L. Kelly and Dr. James Dunlop, both of whom had died during the past year, and who were for many years governors of the hospital. Thereafter the company adjourned to the new wing which was declared open by Mr. Cameron Corbett, M.P. This contains two new operating theatres, a special electricity room, and four wards. The accommodation of the hospital is thus increased to 180 beds —Sir Donald Currie has given £1000 to the Greenock Infirmary.

### *The Aberdeen University Extension Scheme.*

A meeting of the general committee of the Aberdeen University Extension Scheme was held on Jan. 3rd in the Mitchell Hall, Marischal College, for the purpose of receiving a report from the Executive Committee as to the appeal for funds. Principal Lang presided. The honorary treasurers reported that the total amount of subscriptions intimated to them was £26,942 2*s*, of which £5345 had been received. The total number of separate subscriptions may be stated at less than 800 Principal Lang intimated a special subscription of £3000 from Colonel Cooper (Elgin), bringing the total sum up to £29,942 2*s*. With characteristic promptitude Lord Strathcona has transmitted his cheque for £25,000, and this is accompanied by a letter the terms of which clearly indicate the sincere interest which is felt by the Lord Rector in the appeal that has been so warmly supported. The following is an approximate summary of the money subscribed since the present scheme was launched 10 years ago. Result of first appeal: Government grant, £40,000; Dr. Mitchell's contribution, about £36,000; and public subscriptions, £40,000 Result of present appeal: Lord Strathcona's subscription, £25,000; Mr. Charles W. Mitchell, £20,000; public subscriptions, £30,000; and cost of New Greyfriars Church (defrayed by Town Council), £10,000. A total of £200,000 has thus been obtained from all sources. The site of the new front block is being rapidly cleared, whilst the building of the New Greyfriars Church, along the Queen-street side, is being carried on with all speed

### *Arts Class, 1880–1884.*

The sixth triennial reunion of this class was held in the Palace Hotel, Aberdeen, on Jan. 3rd, the Rev. G. M. Reith, Free St. Cuthbert's, Edinburgh, being in the chair. The following medical members of the class were present: Dr. A. T. G Beveridge, Dr A. R. Galloway, Dr. R G McKerron, Dr. J. S. Riddell (Aberdeen), and Dr. G. C. Milligan (Forres). It was resolved to publish the class album prior to next reunion. A very successful meeting closed with the singing of "Auld Lang Syne."

### *Public Health of Dublin.*

THE notes on the "Health of Dublin" and on its death-rate published every week in THE LANCET show that the condition of the city, as appears from the recent returns, has undergone much improvement when compared with the records of former years. There would seem to be a positive, and so far a permanent, improvement in its death-rate—a matter which was much to be desired, for the rate was at one time exceptional and a disgrace to our public health department. Matters have certainly improved and the number of deaths in Dublin can now fairly compare with that of other towns in England or Scotland. Sir Charles Cameron, C.B, medical officer of health of Dublin, stated in connexion with a Local Government Board inquiry on Dec. 17th, 1901, that the public health of Dublin had been much improved by recent expenditure He said that during the period between 1876 and 1880 the death-rate from all causes was 33·3 per cent., and during the decade ending 1900 29·6 We seem still, however, not to have much ground for congratulation Scarlet fever causes many deaths, and diphtheria—which was quite rare in Ireland 10 years ago—is now claiming an increasing number of victims year after year It has gradually invaded this country—coming apparently from England—and it now prevails more especially along our eastern coast. It would thus rather seem as if the bacillus took its trip across the

the next two years he had three attacks of pleurisy in the left side. In 1897, when he came under the care of Dr. Farvarger, he suffered from œdema of the lower extremities and of the skin of the lower part of the abdomen, and dilatation of the right heart. Frequent attacks of erysipelas afterwards occurred in the lower extremities, which commenced to swell more and more. There were no albumin in the urine, no chyluria, and no lymphorrhœa. Repeated examination of the blood proved the absence of any parasites, such as filaria sanguinis. From 1896 onwards the swelling of the lower extremities became enormous, especially on the left side, the circumference of the left leg being 24 inches in May, 1896, 26 inches in July, 1896, and 30 inches in August, 1898. When the patient was shown before the society the following circumferences were measured: left leg (near the malleolus), 24 inches; left calf, 35 inches; lower part of left thigh, 38 inches; upper part of left thigh, 50 inches; right leg (malleolus), 22 inches; calf, 27 inches; and thigh, 19 inches On the back of the left thigh the elephantiasis of the skin formed a tumour of the size of two human heads and there was a second tumour on the left calf. The skin of the affected parts showed the characteristic properties of thickening due to elephantiasis, but the skin of the feet, which showed only slight œdema, was nearly normal. The enormous distension of the limbs was accompanied by a corresponding increase in the patient's weight which amounted to 280 pounds Various therapeutic means had been tried without success and surgical intervention was contemplated.

### *Sanatorium for Tuberculosis in Toronto.*

A FEW weeks ago it was decided by the local board of health of Toronto, on the advice of the medical health officer, that a by-law should be submitted to the people at the coming municipal elections in January for the sum of 50,000 dols. for the purposes of a sanatorium for consumptive patients. Affairs were beginning to get into a tangle between the city health authorities, the Anti-Consumptive League, and the National Sanatorium Association, when the latter came forward with a definite plan of campaign and announced that it would have accommodation for 100 patients from the city of Toronto within a twelvemonth. In the meantime a city physician has addressed a letter to the mayor drawing attention to the fact that the city hospitals have closed their doors against consumptive patients and that these unfortunate individuals practically have to shift for themselves. It appears likely that the hospitals will have to set apart wards for the reception of these patients until the sanatorium is ready to take up the work.

### *Appendicitis in British Columbia.*

At the first annual meeting of the newly organised British Columbia Medical Association Dr. J. C. Davie of Victoria, who was the president of the association, contributed a very interesting and able paper on the subject of appendicitis, the first paper on this subject which has been published by a British Columbian practitioner. The paper appears in the November issue of the *Dominion Medical Monthly* and the cases constitute, without selection, all those which have come to the personal attention of Dr. Davie since the year 1893. During that time he has operated on 105 cases of appendicitis with six deaths and 99 recoveries. Of cases of general septic peritonitis he has had 15, four dying and 11 recovering. Dr. Davie certainly has had excellent results, considering the fact that he never refused to operate even in the worst class of cases.

### *Small-pox in Quebec.*

Under date Nov. 29th the Board of Health of the Province of Quebec has issued a statement showing that in that province there had been 81 places where small-pox had broken out and that in all there had been 340 cases up to that date. In Montreal alone there had been over 30 cases. Numerous and special instructions have from time to time been issued by the Health Department of the province with regard to vaccination of the employés of industrial establishments, pupils at schools, and lumbering men about to go into the woods for the winter's work, but in spite of all contagion continues to spread and the province is threatened with a very extensive outbreak of the disease. One or two cases of tetanus are reported as following on the employment of impure lymph in vaccination. The Health Department recommends only glycerinated vaccine.

### *Toronto Clinical Society.*

At the regular meeting of this society held on Nov. 6th Dr. George A. Bingham and Dr. J. T. Fotheringham reported a case of thyroidectomy in a female, aged 30 years. The operation was performed by Dr. Bingham who made an incision obliquely from the left mastoid process to the sternum, the cavity being obliterated by several rows of catgut sutures by quilting. For subsequent tachycardia both gentlemen spoke very highly of the favourable results obtained by the use of the ice-bag to the præcordia. Dr. J. Algernon Temple reported at the same meeting a case of Paget's disease of the nipple and showed the pathological specimen. He removed the entire breast from an unmarried woman, aged 45 years. There was no glandular enlargement in the breast a year prior to its removal.—At the next regular meeting, held on Dec. 4th, Dr. Graham Chambers showed a man, aged 50 years, an engineer, whom he considered to be the subject of blastomycosis, although as yet he had not been able to demonstrate the fungus under the microscope. The lesions appeared on the nose, the cheeks, the upper lip, and the backs of the hands. They were undergoing marked improvement under large doses of iodide of potassium. An interesting case of menorrhagia which baffled all treatment was reported by Dr. R. B Nevitt, while Dr. A. J. Harrington reported a case of mushroom poisoning with recovery. Dr. J. F. W. Ross, the President, showed several specimens, one being a cystic kidney, while another was a case of double ectopic gestation occurring in a patient at the same time. On one side the pregnancy had advanced to three and a half months and had ruptured; on the other side pregnancy had advanced about a month or six weeks. Although *in extremis* on the operating table the patient made a good recovery. Dr. Ross also reported that ectopic gestation re-occurring in the same patient had been observed by him four times.

### *X-Ray Photographs.*

IN a case of personal injury the Supreme Court of Wisconsin has decided that the rule affecting photographs taken by ordinary process and used in the trial of a cause for the better understanding by the jury of the evidence submitted in the case shall hold good in the case of photographs taken by the x-ray method. The trial judge is to be the one to decide whether or not a photograph is proper in a particular situation upon the trial of the case, and this decision being based upon reasonable ground it must stand In this particular case a physician, qualifying as an expert in taking x-ray photographs, testified that he had made an examination of the patient's wrist and hand by means of the x-ray process and later had taken two photographs which gave a perfectly correct representation of the bones. The photographs were offered and accepted as evidence, notwithstanding the protest of the opponent. The case was that of Mauch *v.* the City of Hartford. The objection was based upon the plea that the pictures were taken without notice to the city or its counsel. The court announced that it knew of no regulation requiring notice of the taking of a photograph to be used by one party in the trial of a cause by the adverse party in order that the latter may be represented at the time of such taking necessary to its acceptance in evidence. It is entirely proper for the trial of causes for some purposes that photographs be exhibited to facilitate the understanding of the jury of some objects otherwise obscure; they are used to enable the court and jury more clearly to understand the particular location or object material to the litigation than could be made lucid by mere oral description or explanation, and the object being quite permissible the court may use its discretion as to whether they shall be admitted. Such a case exists when it is necessary for a non-expert to comprehend the complicated structure of the human anatomy and the presence of foreign bodies in the human body or of any abnormal condition. Since the discovery of the x-ray still under observation. Cultures injected into animals produced a very intense epithelial inflammation which was followed by the formation of adenomata. In reality the microbe brings about increased growth of those cells with which it comes in contact. The cells appear to multiply by a kind of inflammation, but the white corpuscles do not present the usual phagocytic phenomena. There are also to be found in the case of glands in connexion with a tumour, which are swollen but not obviously infected, certain cells full of microbes which are difficult to stain. Dr. Doyen found his "micrococcus neoformans" in the juice from a mammary tumour in a bitch and in the juice of various tumours in human beings, such as sarcomata, cystic tumours of the breast, and in slowly growing and sclerosing epithelial tumours. From these last no cultures could be obtained. All those cases which gave positive results in the culture-tubes were cases in which recurrence occurred with great rapidity. The points of recurrence, secondary tumours and affected glands, yielded similar cultures to those of the original growth. In the case of very malignant tumours cultures were obtained, provided that suitable media were used, in about 24 hours. Subcutaneous injection of the toxin of this microbe, attenuated in a special manner which Dr. Doyen has not yet made public, brings about, especially in the affected glands, a reaction similar to that produced in tuberculous glands by tuberculin Post-operative injection of this toxin has given satisfactory results which have endured for six months, but Dr. Doyen adds that these results must be confirmed by further observations. These injections must not be given in the case of very large rapidly-growing tumours, for in such cases they produce a violent reaction comparable to that brought about in local masses of tubercle by the first tuberculin of Koch. On the other hand, these injections appear to have given good results in patients who have been operated upon and in whom no growth is left as far as can be ascertained. In such cases the injection appears to prevent recurrence.

### *The Laws as to Public Health.*

For more than 10 years the question of a public health regulation has been sent backward and forward between the Chamber of Deputies and the Senate without anything being done. However, on Dec. 16th, 1901, a Bill passed the Chamber of Deputies in a very thin house, and yet none of the ordinary political journals and hardly any of the medical journals even so much as mentioned the fact. But the new law certainly raises very burning questions, for among other points it abolishes the professional secrecy of medical men, at least in part, for they are obliged to notify every case of infectious disease. It attacks personal liberty, for it makes vaccination and revaccination obligatory. It attacks property, for furniture and other personal articles which may be infected have to be destroyed, and it deals with the construction of houses. It also creates new taxes, for the expenses of putting into a hygienic condition or of disinfecting houses and other articles will be met by a charge upon the State or upon departmental or communal bodies.

### *Human Tuberculosis Inoculable in Animals.*

At the meeting of the Academy of Medicine held on Dec. 24th, 1901, M. Arloing reminded the meeting that at the British Congress on Tuberculosis recently held in London Professor Koch had put forward the opinion—an opinion which created a great deal of excitement—that human tuberculosis was totally different from the tuberculosis which occurred in ruminants and so there was no need to fear that tuberculosis could be transmitted from cows and such like animals to man by the agency of milk or meat. Professor Koch specified various differences which exist between human tuberculosis and that of bovine animals. Such differences were admitted by all observers, but they were by no means sufficient to afford grounds for a radical distinction. The two principles upon which Professor Koch based his argument were the following. The bacillus of human tuberculosis could not be inoculated into animals of the bovine, ovine, or porcine species, although the bacillus of bovine tuberculosis readily infected both sheep and pigs. Bovine bacilli, however, did not produce tuberculosis in man M. Arloing had attempted to verify these results and to find out if human tuberculosis could not be transmitted to animals. Using intravenous inoculations of a pure culture of the human tuberculosis bacillus, he had managed to produce certain forms of tuberculosis in 23 animals, such as calves, sheep, goats, asses, and bullocks, which were stated to be immune to human tuberculosis by Professor Koch. There was, therefore, evident ground for saying that the bacillus of human tuberculosis and that of animal tuberculosis were the same as the bacillus of Koch. For the present, then, it was obviously a wise precaution to maintain the various regulations in force with regard to meat and milk which were suspected of containing the tuberculosis bacillus.

Jan. 7th.

## VIENNA.

(FROM OUR OWN CORRESPONDENT.)

### *"Gasu-Basu": a New Local Anæsthetic.*

A NEW local anæsthetic obtained from an Indian plant, called "gasu-basu," has recently been submitted to careful examination by some Hungarian dentists—Professor Arcövy, Dr. T. Madzsar, and Dr. B. Balassa of Budapest. The anæsthetic action of this substance was discovered a year ago by a dentist in Fiume, Dr. D. Dalma, who tried the effect of gasu-basu in cases of painful pulpitis, and recommended it as a powerful agent which might replace arsenic in the treatment of that condition. Dr. Dalma also separated the active principle of the plant, which proved to be an alkaloid, and in his later experiments he used the salt obtained by treating the alkaloid with hydrochloric acid. This salt has been named "nervocidine" and its pharmacological properties have been investigated in Professor von Bokay's laboratory in Budapest by Dr. B. von Fenyvessy who obtained the following results. Nervocidine is a yellow, hygroscopic powder easily soluble in water, less soluble in ether and alcohol. The aqueous solution froths if shaken and gives all the reactions of an alkaloid. Nervocidine is amorphous and cannot be obtained in a crystalline state. In weak solutions (one-tenth or one-twentieth per cent.) nervocidine produced a marked local anæsthesia of the cornea of warm-blooded animals Two drops of a one-twentieth per cent. solution applied to the human conjunctiva produced a burning sensation accompanied by lacrymation and followed after 20 minutes by anæsthesia of the cornea lasting for five hours. After seven hours the cornea regained its normal condition. A one-tenth per cent. solution of nervocidine brushed over the mucous membrane of the cheek caused local anæsthesia of the brushed surface and of the tongue accompanied by loss of the sensation of taste and the perception of touch, but without loss of the perception of heat and cold. Solutions of a strength exceeding one-half per cent. produced irritation of the cornea, and by application of a two per cent. solution to the cornea of rabbits and dogs a severe ulcerative keratitis, lasting from five to 10 days, was produced, but on the twelfth day this keratitis was entirely gone. The anæsthesia of the cornea persisted during the whole course of this keratitis and the sensibility returned with the recovery of the cornea which did not afterwards show any trace of the previous inflammation. Attempts to produce local anæsthesia by subcutaneous injections of nervocidine in animals have not yet been successful. The general action of nervocidine on the system was that of a poison producing death by paralysis of the motor centres of the nervous system and of the peripheric nerves. All the experiments proved that nervocidine was a powerful local anæsthetic which had the advantage of producing a much more sustained action than cocaine, for the effect of a one-half or one-fifth per cent. solution might last for two or three days It is, however, not without its drawbacks, such as the local irritation to which it gives rise, the slow production of the anæsthetic state (from 10 to 20 minutes being required), and a liability to the occurrence of nausea, vomiting, salivation, and other symptoms of general poisoning. Nervocidine is an interesting addition to the list of local anæsthetics, but its practical application is at present restricted to the purposes of dentistry. In the treatment of pulpitis it has been found particularly useful in the Budapest dental clinics.

### *Sporadic Elephantiasis.*

Elephantiasis is very rare in Austria, but an interesting case of this disease was recently shown by Dr. Farvarger at a meeting of the Wiener Gesellschaft der Aerzte. The patient, a young man, aged 25 years, had always resided in an Alpine village, Aussee, in Styria, and had been healthy up to the age of 15 years In the year 1891 he suffered from pleurisy and slight œdema of the feet, and in the course of

VACCINATION AT GLOUCESTER.—At the meeting of the Gloucester Board of Guardians held on Dec. 31st, 1901, it was reported that there were 850 vaccination defaulters in the district between Jan. 1st, 1899, and Sept. 1st, 1901.

CHELSEA HOSPITAL FOR WOMEN.—The new year's entertainment arranged by the ladies' committee for the patients and nurses was given on Jan. 4th, when the following artists kindly gave their services:—Miss Nellie Ganthony, Mr. Lionel Brough, Miss Vera Beringer, Mr. Mercer Adam, Miss Ada Webster, Miss Kinnison, and Mr. Rohan Clency. The wards and corridors were prettily decorated and the patients seemed thoroughly to enjoy the songs, recitations, and musical sketches. The patients' tea had been given on new year's eve, when many of the ladies' committee were present. The nurses held their concert on Dec. 29th.

THE CLERICAL, MEDICAL, AND GENERAL LIFE ASSURANCE SOCIETY.—The bonus report of this society which was presented to the extraordinary meeting held at the offices, 15, St. James's-square, London, S.W., on Jan. 2nd, shows that the society divides the large surplus of £597,415 in respect of the past quinquennium. During the past five years the new assurances amounted to 4043 in number, assuring £2,907,556, as compared with 3810 policies assuring £2,819,894 in the preceding period. The rate of interest earned was very satisfactory in view of the high character of the investments. It increased slightly but steadily in each of the last three years and averaged £3 16*s.* 8*d.* per cent. for the whole period The claims by death were 1437 in number and, including bonuses, £1,143,321 in amount. The total expenses of management were £12 14*s.* 9*d* per cent. of the premiums, as against £13 11*s* per cent. in the preceding period.

THE WOOLWICH, PLUMSTEAD, AND CHARLTON MEDICAL UNION.—At a meeting of the above union held on Dec. 18th, 1901, the following motion was unanimously agreed to:—"That vaccination should be dealt with as a sanitary question affecting the welfare of the community on similar lines to those now in force for the notification of infectious disease, and that it is derogatory and injurious to compel a medical man by law to do an unprofessional act - viz , to call at the houses of his fellow practitioners' patients and offer professional service. The members of this union therefore respectfully submit: first, that vaccination should be placed under the control of the sanitary authority and be removed from the category of Poor-law relief; and, secondly, that the operation and certification of successful public vaccination according to the legal standard should be open to all registered medical practitioners, and that the authorised fee should be payable to such medical practitioners by the sanitary authority in all cases where the legal standard was complied with."

A PATIENT'S PREFERENCE FOR AN UNQUALIFIED MEDICAL MAN AND ITS CONSEQUENCE —The Derby borough coroner (Mr. John Close) recently investigated the circumstances surrounding the death of Charles Nicholson, aged 52 years, who died on Dec. 31st, 1901. The coroner had adjourned the case for inquiries to be made as the result of a communication which he had received from Dr. Parry-Jones, and because Mrs. Nicholson had stated that her husband had been taking medicine and using ointment supplied to him by Captain Feilden, of the Crimson Cross Dispensary. No charges were made for the remedies supplied, but a box was placed against the door at the dispensary so that persons visiting the establishment might make voluntary contributions. The widow of the deceased, in her evidence, stated that Captain Feilden first saw him about 12 months ago. He had called upon him on different occasions and when he saw him the last time about a month previously he told the deceased that he ought to see a medical man. The deceased, however, would not do so. She asked him to have a medical man but he declined. A neighbour also gave evidence as to Nicholson's strong objections to a doctor, and Captain Feilden deposed that he attended the deceased for bronchitis and another complaint. He also had something the matter with his heart and witness advised him to see a doctor.—The Coroner: Then you thought it was a case for a properly qualified practitioner?—Witness: I thought he would require someone to give him a certificate when he died. A doctor was no good for any other reason.—Dr. Parry-Jones deposed to making a post-mortem examination and finding that death was due to aneurysm. In all probability if Nicholson had had a qualified medical man to attend him he would have lived longer as the aneurysm was of long standing.—The Coroner: If he refused to have a doctor what could be done for him?—Dr. Parry-Jones: Nothing. The jury returned a verdict to the effect that death was due to an aneurysm.

DR. C. KILLICK MILLARD, medical officer of health of the borough of Leicester, is the President-elect of the Midland Branch of the Incorporated Society of Medical Officers of Health.

DR. CHARLES A. WEST of Bodmin was, at the Cornwall Quarter Sessions held on Dec. 31st, 1901, appointed visitor to the county prison in the place of the Earl of Mount-Edgcumbe, resigned

DEATH FROM BURNS.—An inquest was held at Exmouth on Dec. 30th, 1901, upon the body of a man who had suffered from gout and was lighting a cigar on Dec. 21st when some cotton-wool which was wrapped round his hands caught fire. He was severely burnt and he died on Dec. 28th. A verdict of "Accidental death" was returned.

THE LATE MR. EDWARD STOCK.—The committee of the Bristol Dispensary in the annual report for 1901 which has just been issued, allude with much regret to the death of Mr. Edward Stock, M.R.C.S. Eng., which occurred at Clevedon, Somerset, on Nov. 18th, 1901. The deceased who was 81 years of age had been for 34 years connected with the Bristol Dispensary, first as secretary and subsequently as a member of the managing committee.

DONATIONS AND BEQUESTS.—By the will of Mr. Henry Duncalfe. M.R.C.S., of Tudor-hill, Sutton Coldfield, Birmingham, £1500 are left in trust to found a "Duncalfe Exhibition" in Sutton Coldfield Grammar School, and £5000 in trust to found a "Duncalfe Benevolent Fund" under the Birmingham Medical Benevolent Society. £5000 have also been left to the Royal Medical Benevolent College at Epsom to found "The Duncalfe Trust," and the income of the sum of £5000 is to be applied for the benefit of unmarried daughters, not under 50 years of age, of medical men. Bequests are left to the Birmingham General Hospital, the Queen's Hospital, the Eye Hospital, the Blind Asylum, the Orthopædic and Spinal Hospital, the Deaf and Dumb Asylum, the Knowle Asylum for Idiots, the Wolverhampton Orphanage, the Llandudno Sanatorium, the Llanfairfechan Convalescent Home for Men, the Royal Alexander Hospital at Rhyl, and the Home for Incurables at Leamington. It is estimated that more than £30,000 will be available fo charitable purposes.

THE NEW GENERAL HOSPITAL, BIRMINGHAM.—At a meeting of the General Committee held at the General Hospital, Birmingham, on Dec. 31st, 1901, a report on the new hospital was read by the honorary secretary, Mr. Walter N. Fisher. He said that the preliminary steps to the erection of the new buildings were formally taken at a meeting held in the town-hall on Jan. 19th, 1891, when a committee with Sir John Holder as chairman was appointed to carry out the scheme. Designs for the new hospital were sent in by 12 selected architects, the consulting architect, Mr. Alfred Waterhouse, R.A., awarding the first place to Mr. William Henman. The builders were Messrs. T. Barnsley and Son. After a careful examination of buildings in which Mr. William Key of Glasgow had introduced the "plenum" system of ventilation combined with steam heating, the committee decided to adopt his methods and to employ his services. The ceremony of laying the foundation-stone was performed on Sept. 8th, 1894, by the Duke and Duchess of York, now the Prince and Princess of Wales, and on July 7th, 1897, the hospital was opened by Princess Christian. In the following October the patients were removed from the old to the new premises. The hospital contains 346 beds, of which 15 were dedicated to the memory of specified individuals The sum required for the dedication of a bed is £1250. The total cost of the hospital, land, heating and ventilating, electric supply, furnishing and fittings, architect's commission, and general expenses was £219,459, as against receipts from subscriptions and bequests amounting to £208,841. The balance is more than covered by the proceeds of the sale of the old hospital and site.

process it has several times been employed in laying bare the human frame and then photographing the appearance thereof, as in the case of ordinary photographs. The courts are bound to use every possible means of discovering the truth, and to that end every new discovery which has passed the experimental stage must be looked upon as a new aid in the administration of justice in the department it covers. The courts have never failed to avail themselves of the art of photography by the x-ray process in proper cases.

### *Insurance against Suits for Malpractice.*

The State Insurance Commission of Minnesota rules that general casualty indemnity companies may write contracts insuring physicians against loss from damages in suits for malpractice. A test case in Massachusetts was the ground of the State officials' decision that such protection is needed, not so much by inexperienced and unskilful physicians as by the best and most successful of their number as a protection against blackmail. It has come to pass in some sections that the frequency of damage suits against physicians and hospitals has rendered the practice of medicine, and especially surgery, absolutely perilous, and some good operators have seriously considered giving up the practice of medicine Many unjust verdicts have been rendered in favour of alleged injured persons and the general public usually favours this class. It has been considered adverse to public policy to put limitations upon such prosecutions or to permit insurance against them; but it would certainly be still more against public policy to allow honest surgery to be discouraged by encouraging blackmail, and popular prejudice is apt to do this very thing. A surgical operation or a medical treatment of a case depends for success upon numerous possibilities beyond the personal control of the practitioner to make their outcome a certainty in any particular case. An unfortunate termination of the case is therefore, as held by the Court of Massachusetts, to be considered an accident in the absence of proof to the contrary, and it is therefore quite legitimate to insure against such a possibility in a casualty insurance company.

### *Tetanus and Vaccination.*

Owing to the public alarm due to deaths from tetanus after vaccination the State Board of Health of Pennsylvania adopted the following motion :—"In view of the very natural public apprehension regarding the possibility of tetanus following vaccination, as illustrated by recent cases of this accident in a neighbouring State, this Board desires to state its conviction, based upon a careful study of vaccination and of the cases referred to, that it has yet to be demonstrated that vaccine virus ever contains or becomes contaminated with the germs of tetanus. When such occurrences as those referred to take place it is because, owing to carelessness usually on the part of the person vaccinated, the germs of tetanus have gained access to the wound on the arm, as they may to any other wound, abrasion, or scratch upon the surface. There is no reason for dreading or abstaining from vaccination because of these recent cases. This is sufficiently demonstrated by the fact that more than half a million persons have been vaccinated in and around the city of Philadelphia within the last few months without the occurrence of a single case of tetanus. Inasmuch as new cases of small-pox are being reported to the Board daily from all parts of the State the present would be a most unfortunate time to interrupt the general vaccination which is now in progress."

### *A Rat Crusade in Honolulu.*

It being a well-established fact that plague is often carried ashore from infected vessels by rats it is wise in the health authorities to inaugurate a crusade against rats when there is little or no plague within their borders. Through the efforts of Dr. Pratt, the executive officer of the Territorial Board of Health, a crusade has been enacted by mapping out Honolulu with an inspector to each district who distributes traps and poison, sees that they are used properly, deodorises the traps, and collects all the rats. The district as a whole is under two superintendents. The method of extermination is confined to traps, poisons, and sulphur fumigation; the rat-bounty methods are not used. All rubbish is cleared up and burned; all warehouses are made air-tight for sulphur fumigation; all inter-island vessels are fumigated; the clearing up of wharves includes cleaning underneath the same. All rats are kept according to districts and examined bacteriologically for the purpose of determining whether or not a certain district is infected and in need of special attention.

Dec. 29th, 1901.

# Obituary.

## HENRY GEORGE MADAN, F.C.S.

ALL students of chemistry, and especially those who studied the science at Eton under the direction of Mr. Henry George Madan, will learn with much regret of his death which took place at Gloucester on Dec. 22nd, 1901. Mr. Madan was born in 1838, and was educated at Marlborough College, where he obtained an open exhibition at Corpus Christi College, Oxford, in 1857. He acted as assistant to Sir Benjamin Brodie for some time, and was then appointed Professor of Chemistry at Queen's College. He was afterwards appointed master in chemistry at Eton, a post which he held for 20 years. He was joint author, with Mr. A. G. Vernon Harcourt of Christ Church, of "Exercises in Practical Chemistry," and wrote also several smaller works on Physics and Chemistry. A short time ago Mr. Madan was knocked down by a railway-truck in the docks at Gloucester, the injuries which he sustained necessitating the amputation of his right arm. He never seemed to recover from the severe shock which he received, his health giving way completely. Mr. Madan was an excellent, able, and impressive teacher. He possessed unusual manual dexterity, was an excellent glass-blower, and a first-rate and clever worker in the laboratory. He was most skilful with the lathe and an accomplished turner. All who came in contact with Mr. Madan preserved the kindliest recollections of him and will hear with sad feelings of the terrible accident which befell him and which undoubtedly hastened his death.

**DEATHS OF EMINENT FOREIGN MEDICAL MEN.**—The deaths of the following eminent foreign medical men are announced :—Dr. Hans Hensen, *privat-docent* of Medicine in the University of Kiel.—Dr. Nicolás Homs y Pascuets, Clinical Professor of Medicine in Barcelona.

# Medical News.

**SOCIETY OF APOTHECARIES OF LONDON.**—At the Primary Examination the following candidate have passed in the subjects indicated :—

PART II.

*Anatomy.*—H. Bennett, Manchester; J. Cree, Belfast; T. L. A. Jones, Cardiff; P. J. Martin, St. Bartholomew's Hospital; and E Renouf, Royal Free Hospital.

*Physiology.*—J Cree, Belfast; E. P. J. Dawes, Birmingham; A. G. C. Findlay, University College Hospital; E. Renouf, Royal Free Hospital, F. A. K. Stuart, St. Mary's Hospital; and T. R. Waltenberg, Manchester.

**FOREIGN UNIVERSITY INTELLIGENCE.**—*Cracow:* Dr. Leon Krynski, *privat-docent* of Operative Medicine, has been promoted to an Extraordinary Professorship.—*Kiel:* Dr. R. Gobell has been recognised as *privat-docent* of Surgery.—*Paris:* Dr. Gilbert, *agrégé*, has been appointed Professor of Therapeutics.

**LOW ANNUAL DEATH-RATE IN CHICAGO.**—During the 51 weeks ended on Dec. 21st, 1901, a total of 23,625 deaths was recorded in Chicago. At this rate the total deaths in Chicago for the year 1901 would not exceed 24,300, and calculated on the minimum mid-year population according to the estimate of the United States Census Office—namely, 1,758,000—the annual death-rate per 1000 for the year would be about 13·8, which is said to be the lowest ever recorded for that or any other city of more than 1,000,000 population The lowest previous rate—based on the United States census figures of population—was 14·36 per 1000 in 1897. For the previous 10 years—i.e., the period 1890–1900—the average mortality-rate was 17·67 per 1000.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, S.E.—Junior Resident Medical Officer and Registrar. Salary £50, with board and washing.

GENERAL HOSPITAL, Birmingham.—House Physician. Salary £50 per annum, with residence, board, and washing. Also House Surgeon. Salary £50 per annum, with board, lodging, and washing.

GLASGOW ROYAL INFIRMARY.—Superintendent. Salary £500 per annum, with board, residence, &c.

HAMPSTEAD HOSPITAL.—Resident Medical Officer for six months. Salary at rate of £120 per annum, with rooms, coals, and gas.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, and board and residence.

JOINT COUNTIES LUNATIC ASYLUM, Talgarth, Breconshire.—Medical Superintendent. Salary £450 per annum, with house, coal, light, and washing.

LONDON HOSPITAL, Whitechapel, E.—Assistant Director of the Pathological Institute. Salary £200 per annum.

LONDON LOCK HOSPITAL.—House Surgeon to Female Hospital. Salary £80 per annum, with board, lodging, and washing.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £70 per annum, with board and residence.

MOUNT VERNON HOSPITAL FOR CONSUMPTION, Hampstead.—Senior Resident Medical Officer. Honorarium £100.

NOBLE'S ISLE OF MAN GENERAL HOSPITAL AND DISPENSARY, Douglas, Isle of Man.—Resident House Surgeon. Salary, £82 per year. with board and washing free.

NORFOLK COUNTY ASYLUM, Thorpe, Norwich.—Junior Assistant Medical Officer, single. Salary £120 per annum, with board, lodging, and washing.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, N.E.—House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and laundry.

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House Surgeon for six months. Salary £50 per annum, with board, lodging, and washing.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, AND ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Research Laboratories.—Assistant Bacteriologist in the Research Laboratories. Salary £200 per annum.

ROYAL HOSPITAL FOR INCURABLES, Putney Heath.—Medical Officer. Salary £250 per annum.

ROYAL INFIRMARY OF EDINBURGH.—Pathologist. Salary £400 per annum.

ROYAL SURREY COUNTY HOSPITAL, Guildford.—Assistant House Surgeon. Salary £75, with board, residence, and laundry.

ST. BARTHOLOMEW'S HOSPITAL.—Assistant Surgeon.

SEACLIFF LUNATIC ASYLUM, Dunedin, New Zealand.—Assistant Medical Officer, unmarried. Salary £250, with board, lodging, and washing.

SEAMEN'S HOSPITAL SOCIETY (Dreadnought), S.E.—House Surgeon for Society's Branch Hospital, Royal Victoria and Albert Docks, E. Salary £50 per annum, with board and residence.

SCALEBOR PARK, Burley-in-Wharfedale.—Medical Superintendent. Salary £500 a year, with house, board, and attendance.

TOTTENHAM HOSPITAL.—House Surgeon. Salary £50 per annum, with board, residence, laundry, &c.

UNIVERSITY OF ST. ANDREWS.—Examiner in Physiology and Pathology.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Junior House Surgeon. Salary £50 per annum, with board, lodging, washing, and attendance.

WEST HERTS INFIRMARY, Hemel Hempstead.—House Surgeon, unmarried. Salary £100 per annum, with rooms, board, fire, lights, washing, and attendance.

WHITECHAPEL UNION INFIRMARY, Vallance road, N.E.—First Assistant Resident Medical Officer. Salary £130 per annum, rising to £150, with rations, apartments, coal, gas, and washing.

YORK COUNTY HOSPITAL.—Assistant House Surgeon. Salary £80 per annum, with board, residence, and washing.

# Births, Marriages, and Deaths.

## BIRTHS.

CARRUTHERS.—On Jan. 6th, at Halton, Cheshire, the wife of W. Hodgson Carruthers, M.D., of a daughter.

GIBSON.—On Jan. 3rd, at Queen's crescent, Glasgow, W., the wife of E. Arthur Gibson, M.D. Glasg., of a son.

HARDING.—On Dec. 31st, 1901, at Whittlesea, Cambs, the wife of C. Headley Harding, M.R.C.S., L.R.C.P. Lond., of a daughter.

## MARRIAGE.

VAN SOMEREN—FLETCHER.—On Jan. 2nd, at the parish church, Northwood, by the Rev. E. B. Backhouse, Ernest Herbert van Someren, M.R.C.S., L.R.C.P. Lond., of Venice, Italy, to Grace Ivy Ethel, daughter of Mr. and Mrs. Horace Fletcher, of Palazzo Saibante, Venice, Italy.

## DEATH.

CARRINGTON.—On Dec. 26th, 1901, suddenly, at Battersea rise, S.W., William Henry Carrington, L.S.A., L.R.C.P. Irel.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answ to Correspondents.

## THE CLAMOND GAS RADIATOR.

WE have been favoured with a copy of the following letter which believe has already appeared in the *Journal of Gas Lighting.* T writer addresses us "on behalf of the Richmond Gas Stove a Meter Co."

### CLAMOND FIRES—"LANCET TESTS."

*To the Editors of* THE LANCET.

DEAR SIRS,—THE LANCET of Nov. 30th contained a report of w purported to be an exhaustive series of analytical tests of the ab named fires or radiators.

Some of the data, and the conclusions drawn therefrom, wer "peculiar" that while they may pass unchallenged in THE LAN (it not being a technical journal) I quite expected to see th questioned in the practical press.

Had the report been an ordinary "sympathetic" descriptio some novelty a little "poetic liberty" might well pass unchalle but published as these tables and detailed explanations are, w the seal of "THE LANCET Laboratory" upon them, they will, un questioned, be taken by many as reliable scientific results.

It is due, therefore, to the public, and in justice to the whol the gas stove trade, that some of the discrepancies contai the report in question be exposed and corrected.

Gas experts who read the report will have already noted som these errors; no doubt their confidence in the rest would thereby b shaken.

For instance, Table I. informs us that, with 3″ pressure of gas a certain fixed aperture in a burner passes 22 ft. of gas per hour Table II. informs us that the same aperture with 2″ pressure passes 20 ft. per hour—i.e., for 1″ more pressure *only 2 ft. in 20 ft.* more gas?

Tables III. and IV., however, show results much more "peculiar than that, for in them we are told that the same burner which passes 20 ft. per hour at 2″ pressure, *passes only 18 ft. when pressure is increased to 2½″*.

Surely something has gone wrong with THE LANCET meter.

The next "peculiar" result to be noted is the discovery that the hot air chamber which forms the upper part of one of the stoves, and which is heated by the products of combustion before they enter the flue, is of no use, and that the stove without such additional radiating and convecting power is quite as efficient.

If this is true, here is a new law of heat from THE LANCET Laboratory which may seriously upset the calculations of heating engineers, as from it we may prove that a hot radiator gives off no heat, either radiant or convected.

Another very important omission from THE LANCET tests, especially if the results are intended to be of service outside London, is that lower pressures—viz., 1½ and 1″ (the latter of which is prevalent as day pressure in the country)—are entirely ignored.

It is well known that it is at low pressures that most of the present difficulties arise, and if in this direction lies the weakness of the fires in question that fact should be made known in the places where high pressure is not available.

Passing from necessary criticisms of unreliable experiments to practical facts every right-minded progressive producer of articles of such public utility will hail with pleasure each step made towards greater perfection in appliances as they tend to stimulate their more extensive use and inspire the inventive faculties of the craft to "reach another niche the higher."

Yours faithfully,
E. W. T. RICHMOND
(On behalf of the Richmond Gas Stove and Meter Co.).
Dec. 19th, 1901.

⁂ Mr. Richmond's discursive observations—we cannot regard them as criticisms—call for little attention, coming as they do from an interested person addressing us "on behalf of the Richmond Gas stove and Meter Co." We can, however, give him a better reason than that which he supplies why "the data and the conclusions drawn therefrom" have passed "unchallenged"; why, in fact, no one save himself has thought fit to describe them as "peculiar." That reason is taps. We observe that Mr. Richmond, while not suggesting that there is any mistake in our observations on health points—such as the effect of gas-stoves upon the air, the estimation of carbonic acid, the minute detection of carbonic oxide, the composition of the gases at various points—insinuates that here also we must be wrong because of our errors which he says have been noted by gas experts. No errors have been noted by any gas experts, unless Mr. Richmond is such an one. The question of the relation of pressure to consumption in the Clamond Gas Radiators seems to have puzzled Mr. Richmond to such an extent that he has lost his manners. The solution of the mystery of course is taps, all Mr. Richmond's insistence upon the "same aperture" and a "fixed aperture" being beside the point. Mr. Richmond's meter, we may assume, will record the

**ROYAL INSTITUTION** —The Christmas lectures this year consisted of six lectures (adapted to a juvenile auditory) on Waves and Ripples in Water, Air, and Æther, delivered by Professor J A Fleming, professor of electrical ngineering in University College, London At the second ecture delivered on Dec 31st, 1901, the formation of waves n water by the motion of ships and boats was explained At the fourth lecture delivered on Jan 4th, numerous experiments were performed illustrating the principles of acoustic resonance and the structure of musical chords, and a lady played on Mr Stroh's recently invented violin This nstrument, the tone and quality of which are almost dentical with that of a violin of the ordinary construction s, however, of a very dissimilar appearance Four strings of the usual description are stretched on a stout rod or bar which may be, but is not necessarily, of wood There is no hollow wooden body or sounding box The strings are tuned and played on in the usual way and pass over a bridge of the ordinary shape, having a slight lateral rocking motion on the bar against which it rests A bent arm attached to one end of the bridge conveys the vibrations of the strings to the centre of an extremely obtuse cone of thin aluminium about five inches in diameter The resonance of the instrument is produced by this metallic surface aided by a metallic bell about 12 or 13 inches long and six and a half inches in diameter at the open end

MCCANN, FREDERICK M D Edin , F R C S Eng , M R C P Lond , has been appointed Physician to In Patients at the Samaritan Free Hospital for Women London

MUDD, FRANK BURNAND has been appointed Honorary Anæsthetist to the Throat Hospital Golden square

OWEN, EDMUND F R C S has been appointed Consulting Surgeon and Surgeon in Chief to the French Hospital and Dispensary, vice the late Sir William Mac Cormac

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index)*

BOROUGH OF BOOTLE HOSPITAL FOR INFECTIOUS DISEASES —Resident Medical Officer, unmarried Salary £120 per annum, with board, washing and apartments

BOROUGH OF DONCASTER BALBY WITH HEXTHORPE, AND WHEATLEY —Medical Officer of Health and Doctor to Infectious and Small pox Hospitals Salary as Medical Officer £300 per annum, as Doctor to Hospitals £50 per annum

BRADFORD ROYAL INFIRMARY —Dispensary Surgeon, single Salary £100 per annum with board and residence

BRISTOL GENERAL HOSPITAL —Surgeon Also Assistant Surgeon

CHARING-CROSS HOSPITAL —Third Anæsthetist

CHELTENHAM GENERAL HOSPITAL —House Surgeon, unmarried Salary £80 per annum with board and apartments

CHILDREN'S HOSPITAL, Sheffield (Out patient Department) —Lady House Surgeon Salary £70 a year, with board, lodging, and washing

CORPORATION OF LONDON —Female Sanitary Inspector Salary £125 per annum rising to £150

DERBYSHIRE ROYAL INFIRMARY Derby —Assistant House Surgeon for six months Salary of £30 for the six months, with board, residence and washing

DERWENT VALLEY WATER BOARD WORKMEN'S VILLAGE, Birchinlee, North Derbyshire —Medical Officer

DEVONSHIRE HOSPITAL, Buxton, Derbyshire —House Surgeon and Assistant House Surgeon Salary, House Surgeon £100 per annum, Assistant £50 per annum with apartments, board, and lodging

DURHAM COUNTY ASYLUM —Junior Assistant Medical Officer Salary £140 rising to £160, with board, laundry, and attendance called out as if in pain and seemed at times to be strangling. Towards 11 A.M. the symptoms seemed to subside, although the eye still remained swollen, apparently almost bursting. Renewed hot fomentations seemed to relieve this, and in the course of the afternoon violent sneezing and running from the nose were continued for three or four hours, and after this the symptoms seemed to improve. Later in the evening sharp headache set in, probably the result of the alcohol that had been taken, as it was promptly relieved by 15 grs. of phenacetin. A hot bath with hot local applications seemed to soothe the patient as the evening advanced, and he had a fairly good night. The next morning all the pain had practically disappeared, although the left eye was still tumid. At no time during the attack was there any exudation or running of any kind from the swollen and inflamed left eye. In the afternoon of the first day the temperature was 101·5° F. and the pulse was 83, the patient's normal pulse being about 70. The next day the patient appeared perfectly well, the left eye being quite normal in appearance. It is noteworthy that when the pain in the throat was worst and the feeling suggested suffocation and great swelling of the tissues there was not the slightest difficulty in swallowing either then or throughout the attack. I am, Sirs, yours faithfully,

Dec. 30th, 1901. PUZZLED.

⁂ It is naturally difficult to diagnose a case without having seen it. We would suggest that it was a case of angio-neurotic œdema of doubtful origin.—ED. L.

### GUESS-WORK.

*To the Editors of* THE LANCET.

SIRS,—Can you or any readers of THE LANCET kindly inform me, through the medium of your correspondence columns, the probable increase of income likely to be derived from the second and third years' working of a new practice in London amongst the middle classes in proportion to that realised the first year?

I am, Sirs, yours faithfully,

Jan. 1st, 1902. E. W. N.

⁂ Increase of practice depends upon so many factors, to say nothing of the practitioner's individuality, that "E. W. N." must not expect to get any definite information. We publish his request to his fellow-practitioners, however.—ED. L.

### CHARITY AND DENTISTRY.

THE following advertisement appeared in the *Church Times* of Dec. 20th:—

> A LADY will have much pleasure (out of gratitude) in recommending her DENTIST. She can speak well of his abilities and kind treatment, having previously been under the care of three dentists, all of whom made a failure of her teeth. Card sent with pleasure.—Address, T., 3, Radnor-place, Hyde Park, London, W.

We thought that this was a chance not to be missed, so we wrote to "T." She kindly enclosed us the card of a gentleman who, according to the *Dentists' Register*, has one qualification only, but that we may say a valuable one—namely, experience. He was in practice before 1878. Gratitude is a great quality, but why should "T" show her gratitude by advertising her dentist at 4*s.* 6*d.* per insertion? Why not send him a cheese or a turkey, or emulate the good deeds of the Pilgrims who, according to Mr. W. S. Gilbert, waited on Pasha Bailey Ben as thus:—

"They brought him onions strung on ropes,
And cold boiled beef, and telescopes,
And balls of string, and shrimps and guns,
And chops, and tacks, and hats, and buns.

They brought him white kid gloves, and pails,
And candlesticks, and potted quails,
And capstan bars, and scales and weights,
And ornaments for empty grates."

A gift of all or any of these would be a legitimate way of rewarding a dentist or anybody else. "T" being a non-professional person cannot be expected to know professional proprieties, but really the dentist in question has been in practice quite long enough (before 1878) to know that it is not fitting that his cards should be distributed as per advertisement by "T" or any other person.

### THE CASE OF THE LATE MR. W. K. BROCK.

THE following further subscriptions to this fund are announced:—Mr. A. Tuxford, Boston, Lincs., £2 2*s.*; THE LANCET Relief Fund, £12 10*s.*

◆

*General Practitioner.*—The Coroners Act of 1887 was a consolidating Act and did not abolish the essential clauses of previous Acts. If a person dies as the result of an accident the coroner is bound to hold an inquest. If a person dies within such time from the date of an accident as to render it reasonable to infer that the accident might have contributed to the death the coroner must hold an inquest. In the case mentioned only about 12 days elapsed between the accident and the death. In our opinion, as death was attributed to blocking of a large cerebral blood-vessel, it is not improbable that the shock and the sudden confinement to bed of the patient, who had previously led an active life, had some part in causing the fatal issue. We think the coroner was quite justified in holding an inquest. However strong may be the belief of a medical man that death resulted solely from natural causes it is certainly politic to communicate the facts of the accident and the death to the coroner and so to divest himself of all further legal responsibility.

*Q. E. D.*—B cannot take any vigorous steps to enforce a claim against A. The proposal of A to assist B in the management of the practice and to allow his (A's) name to remain on the premises amounted to a scheme between A and B to cover unqualified practice in dentistry. The General Medical Council would condemn the action of both, and no court of law would be likely to view B's claim for damages favourably. But while it was wrong of A to make an immoral bargain we certainly do not think it right of him to benefit pecuniarily by not keeping that bargain. More than this we cannot say.

*G. P.*—Our correspondent is at perfect liberty to analyse the preparation and to write out in testimonial form what he finds. Such a testimonial, however, must certainly not appear on the labels of the bottles unless merely the results of the examination are given without any signature, and this, of course, would render the analysis valueless.

*B. B.*—The second-class examination of the College of Preceptors is no longer accepted by the General Medical Council.

*Coccus.*—Epidemic Diarrhœa, by Dr. F. W. Andrewes, THE LANCET, Jan. 7th, 1899, p. 8; Epidemic Colitis, THE LANCET, Sept. 23rd, 1899, p. 850.

*Y. M. J. H.*—We shall be happy to make an examination of the preparation in question if a specimen is forwarded to us.

*T. D.*—We are not prepared to advocate, at any rate at the present moment, the formation of such a society.

*S. W.*—Our correspondent should consult his usual medical attendant.

*W. N. W.*—We do not know.

## Medical Diary for the ensuing Week.

### OPERATIONS.

#### METROPOLITAN HOSPITALS.

**MONDAY** (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.) St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.) West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY** (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**WEDNESDAY** (15th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

**THURSDAY** (16th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.) St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**FRIDAY** (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopædic (2.30 P.M.).

**SATURDAY** (18th).—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

### SOCIETIES.

**MONDAY** (13th).—MEDICAL SOCIETY OF LONDON (11, Chandos street, Cavendish square, W.).—8.30 P.M. Paper:—Mr. Mayo Robson: Observations on the Surgical Treatment of Obstructive Jaundice, resulting from an Experience of over 200 Operations.

SOCIETY OF ARTS.—8 P.M. Dr. S. Rideal: The Purification and Sterilisation of Water. (Cantor Lecture.)

**TUESDAY** (14th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Adjourned Discussion on Dr. S. M. Copeman's paper on Modern Methods of Vaccination and their same fact as ours—namely that when taps are partly turned off a smaller consumption will be registered, the pressure remaining the same or it may even be increasing These taps were used in the experiments in order to arrive at the maximum and minimum efficiency of the stove as is plainly indicated in the report The *pressures recorded refer merely to the supply, which is variable* The importance of an efficient pressure was also pointed out whereas Mr Richmond says it was ' entirely ignored Mr Richmond need not trouble to search for new physical laws, the application of well established principles to improvements in gas stoves has by no means been exhausted as the little progress made during the last 10 years by gas stove makers abundantly shows —ED L

## LOCUM TENENTS AND ASSISTANTS FEES

*To the Editors of* THE LANCET.

SIRS —It seems to me that the time has come when some change ıould be made in fees paid to men holding temporary charge My object ı drawing attention to this matter is to ask if men who like myself evote their whole time to locum and other temporary work will let me now what are their views on the subject Ever since the days of *r Baxter Langley there has been no recognised alteration made in these* es I think I am right in saying that some of the leading medical gents are of opinion that something definite should be done to increase ıese fees I am informed that dental surgeons have some difficulty in btaining locums even at £5 5s per week Why should medical men ıke less? If I find I obtain suitable replies to this communication I ill decide what future action should be taken to give expression to ıe general consensus of opinion of locum tenents and temporary ssistants —I am Sirs yours faithfully,

T HOWARD BROCKLEHURST M R C S Eng L S A

Weymouth Dorset Dec 30th 1901

## A CORRECTION

*To the Editors of* THE LANCET

SIRS —By an error my new address is given in Churchill s Medical irectory as 70A Grosvenor-square instead of Grosvenor street As ıe wrong address may obviously give rise to the greatest incon enience may I ask the hospitality of your columns to draw attention the oversight I am Sirs yours faithfully

Jan 7th 1902 D WALSH

## FRIENDLY SOCIETIES AND THEIR MEDICAL AID INSTITUTIONS

*To the Editors of* THE LANCET

*SIRS* —Mr J D Pike s letter in THE LANCET of Dec 7th 1901, 1643 has evidently touched C W on the raw even to the xtent of compelling him to seek medical advice which how ver judging from the tone of his reply to Mr Pike in THE LANCET f Dec 14th 1901 p 1709 has not been so much judicious as xtensive As your excellent motto Audi alteram partem is such a ood working text I trust that C W will forgive me when I inform ım that *every medical gentleman* I have *come across* who has read is first letter agrees absolutely with Mr Pike s criticism of its tone ur profession is unfortunately quite alive to the fact that these ıstitutions are legalised robbers and are moreover assisted by the tate in their efforts to pauperise the public as well as the profession t would however puzzle C W to point out an Act of Parliament which compels medical men to accept the posts of surgeons to such ıstitutions whilst *on the other hand* he would have no trouble n finding many proofs of the growing feeling in the profession hat the acceptance of such posts is detrimental to the honour f the medical profession as well as to the best interests of the ublic themselves Even the medical worm will claim its proverbial ight to turn long suffering though it has been Audi alteram artem once more Let me tell C W ' how I feel about the matter *nd assure him at the same time those feelings* are shared by a daily ncreasing majority of the profession Taking club practice in its ecuniary relation to the profession frankly it does not pay and owadays with persons in a decent position not only not ashamed o but eagerly demanding medical care at charity rates for men omen and children it is absolutely ruinous to general practice hould however a medical man have the temerity to protest gainst his daily bread being snatched *from him* 'what happens? C W *tells us (it is very simple) join together and starve him* ill he learns his place, that is what it amounts to and what is ractically attempted wherever these institutes are established

The friendly societies tried it on in Great Yarmouth but C W ill be glad to learn that they have not succeeded in injuring anybody ut themselves The local profession have been on the other hand enefited by the formation of the *institute* and *it is* the daily experi nce of the Yarmouth medical men to have the institute members ome to them as private patients in spite of the better attention and better drugs" offered by the institute This is simply due to the act that the Yarmouth medical men combined together and would not e crushed let the Rotherham medical men do the same and they ill find that they will be the gainers and not the losers by the ormation of the institute *In conclusion* one word more to C W " Once a club joins an institute amalgamation it loses ll control over its medical advisers (other than that exercised by ts representative on the institute committee) and were it not or this fact I am firmly of opinion that the majority of the clubs would gladly leave the Yarmouth Institute and return to their old medical advisers The argument advanced by C W that these institutions are self supporting because their members through the clubs subscribe to the hospitals is fallacious That this is so can be easily proved by looking at any hospital report when it will be found *that however largely the working classes subscribe (and they ought to* subscribe largely) they receive from the charity a great deal more than they subscribe to say nothing of the gratuitous medical and surgical help which is freely given by the very profession C W ' and his kind are so ready to trample on Until the rulers of our profession can see their way to condemn medical men for underselling their brethren and sacrificing their independence to the whims of 'C W s committees there is only one course for the profession to adopt and that is to leave the friendly societies and their medical aid institutions severely *alone* *I am Sirs yours faithfully,*

Great Yarmouth Dec 15th 1901 ALBAN HY MOXON

## THE CASE OF THE LATE MR R B ANDERSON

*To the Editors of* THE LANCET

SIRS —I shall be obliged if you will publish the inclosed list of *those who have been kind enough to respond to my appeal on behalf* of the fund for the benefit of the wife and family of the late R B Anderson F R C S There are still thousands of medical men who know of the circumstances of this case and who ought to feel it a privilege to send a few shillings to the fund The attitude of the men who are supposed to take an interest in medical politics is very disappointing How anyone of them can refrain from adding his mite in memory of the man who sacrificed everything in defending the honour and interests of the profession is a mystery to me Let me *implore them before* this fund is closed to do a little for the *credit of* the profession in this matter I am Sirs yours faithfully

Jan 7th 1902 ALFRED COX

*To the Editors of* THE LANCET

SIRS —Owing to several requests and conditional promises of sub scriptions the committee has resolved to keep this fund open till the last day of February next instead of closing it to-day (Jan 8th) as previously announced

WALTER MORNINGTON *Honorary Secretary*

7 Fig tree-court Temple E C Jan 8th 1902

## A DISCLAIMER

WE have been requested by Mr James Startin to state that he is in no way connected with the letters that have appeared in the lay press under the *nom de plume* of a surgeon to the Roentgen Ray department of the *London Skin Hospital*

## A CASE FOR DIAGNOSIS

*To the Editors of* THE LANCET

SIRS —I should be *greatly obliged by suggestions as to the causation* and treatment of the following (to me) mysterious case A B went to bed about 1 A M in apparently better health and spirits than he had enjoyed for a month in fact feeling perfectly well He had during the previous three or four weeks suffered twinges of what appeared to be muscular rheumatism He was awakened from a sound sleep at about 3 30 to 4 A M by acute agony in the region of the throat accompanied by what might be *referred or echo pains through the whole of the head but particularly* in the jaws and neck He got up tried to examine his throat with a glass, but could see nothing, the agony rapidly becoming more severe In a few minutes the left eye became acutely inflamed with sharp pain and presently began to swell rapidly till the whole of the eyelids and surrounding tissues were bulging out to almost the size of an egg He attempted to relieve himself by *bathing his head* and eye and gargling his throat with hot water without any result The symptoms became so bad that suffocation threatened and the danger appeared so real and imminent that before calling for help he made pencil memoranda of various uncompleted business matters in the belief that he was dying The pains then seemed to spread more *or less throughout the body, but nothing like* so acute as in the head When help came hot fomentations were again *administered* as by this time the patient was incapable of helping himself, and a large dose of hot brandy and water was taken this seemed to cause relief or at least intoxication and pending the coming of a medical man another large dose of hot brandy and water was taken This resulted in a troubled and heavy sleep during which the patient

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris

Scientific Basis, opened by Dr. T. D. Acland and taken part in by Dr. Greenwood, Dr. S. Coupland, Dr. Eddowes, Dr L. Parkes, Mr. H. A. Stonham, Dr. A. E. Cope, Dr. J. Loane, and Prof. Sims Woodhead. Dr Copeman will illustrate his remarks by lantern slides to be shown on Zeiss's Epidiascope. (This will be the first public demonstration of the Epidiascope )

EDNESDAY (15th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—8 P.M. *The President will deliver his Annual Address*

ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Great George street, S.W.) —7.45 P.M. Annual General Meeting.

HURSDAY (16th).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne street, Edgware-road, W.).—8 P.M. Annual General Meeting. Election of Officers. President's Address. Annual Conversazione.

GUTHRIE SOCIETY (Board Room, Westminster Hospital).—8 30 P M. Dr. Hall-Edwards: The X Rays in South Africa (illustrated by lantern slides).

RIDAY (17th).—EPIDEMIOLOGICAL SOCIETY (11, Chandos street, Cavendish-square, W.).—8 30 P.M. Meeting

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (Evelina Hospital).—5 30 P M. Cases will be shown by Mr. A. H. Tubby, Mr. J. J. Clarke, Mr. Walter Edmunds, Dr. G. Carpenter, and Mr. F. C. Abbott. *Papers.—Dr. L. Marshall (Nottingham): A Case of Thyroid* Dislocation of the Hip in a Child.—Dr. L A. Milligan: A Note on a *Case of Chronic Granular Nephritis in a Child, aged seven years.*

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ONDAY (13th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P M. Dr. J. Galloway: Clinique (Skin.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.) —5 P.M. Mr. Baldwin. Surgical Emergencies

UESDAY (14th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Dr. S. Taylor: Clinique. (Medical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Beddard. Traumatic Neurasthenia.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3 30 P.M Dr. Beevor. Muscular Atrophy.

EDNESDAY (15th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C ).—4 P.M. Mr. P. J. Freyer: Clinique. (Surgical.)

*POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-*road, W.).—5 P.M. Mr. McAdam Eccles: Lantern Demonstration *on Hernia.*

HURSDAY (16th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC *(22, Chenies-street, W.C.).—4 P M. Clinique (Surgical.)*

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W ).—5 P M. Mr. Dunn: Conjunctival Diseases.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Waterhouse: Surgical Cases. (Post-Graduate Course.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Garrod Demonstration of Selected Cases.

RIDAY (17th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Mr. M. Gunn: Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Diagnosis of Disease of Spinal Cord, illustrated by Cases.

## EDITORIAL NOTICES.

IT is most important that communications relating to the ditorial business of THE LANCET should be addressed *xclusively* "TO THE EDITORS," and not in any case to any entleman who may be supposed to be connected with the ditorial staff. It is urgently necessary that attention be iven to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1901, which was completed with the issue of Dec. 28th, and the Title-page to the Volume, were given in THE LANCET of Jan 4th.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s* , by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c , should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... . | £1 12 6 | One Year ... ... ... | £1 14 8 |
| Six Months ... ... ... | 0 16 3 | Six Months ... ... .. | 0 17 4 |
| Three Months .. . | 0 8 2 | Three Months ... ... | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

# A Post-Graduate Lecture

ON

# OCULAR PAIN: ITS SIGNIFICANCE, VARIETIES, AND TREATMENT.

*Delivered at the West London Post-Graduate College on June 17th, 1901,*

By PERCY DUNN, F.R.C.S. Eng.,

OPHTHALMIC SURGEON TO THE WEST LONDON HOSPITAL, LECTURER ON OPHTHALMOLOGY AT THE WEST LONDON POST-GRADUATE COLLEGE.

---

Gentlemen,—The ideal subject for a post-graduate lecture, as I have observed here on a former occasion, is one which does not trench upon the province of the text-book; one which has for its basis practical facts easily lending themselves to assimilation by others; and one which does not travel beyond the limits of ordinary experience, thus avoiding the risk of making the discourse an academic display of knowledge possessing but little practical utility In endeavouring, then, to fulfil this ideal I shall occupy your time this afternoon with a practical, and what I hope will prove to be profitable, discussion upon the subject of "Ocular Pain: its Significance, Varieties, and Treatment"

First let us briefly consider the channel by means of which the human eye is endowed with common sensation. In this connexion it seems to be a marvellous fact that the sensory nerve-supply of the eye should be solely derived from a small branch of the nasal nerve which, as you know, arises from the first division of the fifth pair. I say marvellous, for surely it might have been the case that an organ of such importance as the eye would have been provided with a special sensory nerve for itself, or at all events that more than one small sensory branch would have been supplied to it to ensure against the contingency of interruption of the main source of supply. We can only conclude, however, that nature in making things as they are knew her own business. Presumably it was not needful to establish a complicated system of inter-communication with sensory branches, while, on the other hand, in the interests of the eye itself it was merely essential to combine its sensory supply with that of the adjoining nasal cavity. The influence of this connexion is mainly manifested when the eye is exposed suddenly to a brilliant light Under ordinary circumstances the exposure of the eye to light is provided for by the contraction of the pupil, and such contraction is no doubt amply sufficient to protect the retina from harm. But let anyone turn his eyes upwards to the shining sun at noonday, and, as we know, the act is interrupted almost immediately by the occurrence of sneezing The explanation of this phenomenon I believe to be stimulation of the nerve-supply of the cornea This seems to be reasonable, for while the retina is protected from harm by the contracted pupil the cornea would soon suffer were the exposure to the sun to be continued. The strong sensory impression caused by the sun's rays upon the corneal plexus is conveyed by the ciliary nerves to the central nucleus in the brain, with the result that the reflex act of sneezing is induced—an act with which is associated involuntary closure of the lids, and consequently the cessation of the exposure of the eyes to the source of irritation But this reflex act is also, and with perhaps greater interest, illustrated when a child with acute blepharospasm is placed under chloroform for the purpose of having the eyes examined. In these cases you will recall that as soon as unconsciousness is induced and the eyelids are retracted so as to expose the cornea not infrequently sneezing follows Here, however, the light would be only relatively brilliant, inasmuch as the ordinary daylight in a room is sufficient to induce the sneezing. Nevertheless, it must be borne in mind that the child may not have had the eyes open for several days

I have alluded to the protection afforded the retina by the contraction of the pupil on the exposure of the eyes to light, and it is not without interest to recall how this contraction takes place. It is, of course, a reflex act; the optic nerve is stimulated by light and the pupil contracts by the impression being transmitted to the motor oculi. That is to say, the optic nerve, although a nerve of special sense, plays the part of one of common sensation. There cannot, however, be any sensory fibres, so-called, in the optic nerve, otherwise we would expect that papillitis and other inflammatory conditions of the nerve would be accompanied by pain. Thus it is of interest to note in this connexion that a nerve of special sense has been endowed with the characteristics of one of common sensation without possessing any sensory fibres How duly in accord, however, with ordinary physiological principles it would have been had this reflex act been dependent upon stimulation of the corneal plexus: the afferent and efferent paths of the nerve impulse would then be distinctly plain, and the result doubtless would be just as satisfactory as that which now obtains. These observations might seem to suggest that nature had failed to be as wise as she might have been in regard to these pupillary arrangements Therefore, to pursue this matter farther would be merely equivalent to indulging in unprofitable speculation.

Generally speaking, it may be said that pain is an invaluable symptom, and oftentimes the saving clause, in an eye which is the subject of disease. Without it, as I shall proceed to show, patients would, indeed, fare badly. It teaches us many important lessons and provides us with many a clue to treatment Take, for example, a case of acute glaucoma It is not the loss of vision which compels the patients in these cases to seek advice; that is to them of secondary importance in comparison with the intense and agonising suffering with which the disease is commonly associated. Moreover, the surgeon knows that the greater the pain the more serious is the case and the greater the need for immediate interference. Thus the pain of a glaucomatous attack is the index of the peril to which the eye is subjected and marks out the line of treatment. Then, too, in the case of iritis, as long as the pain continues in these cases no improvement can be expected; on the other hand, the cessation of pain indicates the commencement of the retrocession of the disease and the progress towards recovery. Thus it is with most ocular affections—so much so that apart from diseases of the fundus, which are not painful, it may be said generally that the absence of pain in inflammatory conditions of the eye may be regarded as a favourable sign

So much, then, for the significance of ocular pain. I have now to consider its varieties, and I mean by this the different diseases of the eye in which pain is a prominent symptom Ocular pain varies in intensity and it varies with the disease, for example, very little pain occurs in connexion with conjunctival affections—a fact which is not difficult of explanation. The conjunctiva is only sparsely endowed with common sensation Moreover, it is a very distensile membrane which, when inflamed, is capable of being easily stretched. Thus the sensory branches distributed to it are not compressed in any way and are consequently not irritated The sensory nerve-supply of the conjunctiva is derived almost entirely from the lacrymal branch of the ophthalmic division of the fifth, and it is not without significance to note that no direct communication appears to exist between the nerve supply of this membrane and that of the intraocular tissues. Perhaps we may assume that nature designedly kept the two sensory sources separate and distinct Reflect for a moment what the result would be were the ciliary nerves, after supplying the ciliary body and the iris, to be continued onwards into the conjunctiva. Obviously upon every occasion that the conjunctiva was exposed to irritation and became inflamed the ciliary nerves could not fail to be involved in the disturbing or morbid process, as well as the structures to which they were distributed, thus exposing the eye and the vision to repeated and serious risks. Again, the fact that this separate sensory nerve-supply exists is significant in view of the free communication which prevails between both the extra-ocular and intra-ocular lymphatic systems. The lymph spaces of the conjunctiva freely communicate with those of the cornea, and it is doubtless through these lymph channels that solutions of atropine and other drugs, when instilled into the conjunctival sac, reach the anterior chamber. Furthermore, the blood-vessels of the conjunctiva freely anastomose with the ciliary arteries, thus establishing the union between the extra-ocular and intra-ocular vascular systems.

The next structure to be considered in connexion with ocular pain is the cornea. There is, perhaps, no other tissue in the body so richly endowed with common sensation as is this The cornea has been well described as the object lens of the ocular camera The importance, therefore, of its unction is such that nature has taken especial care to rotect it from harm by enabling it to resent the slightest isturbance of its integrity. The simplest example of this igilance displayed by the cornea is when a foreign body nds its way under the upper lid. In these cases often acute ain is felt, and the pain is an invaluable symptom inasmuch s it leads to the immediate detection of the trouble and thus ecures the removal of a source of danger to the cornea. The same is true in cases in which a foreign body becomes ixed upon the corneal surface. No relief is obtained until he foreign substance has been removed and the cornea is xposed to various risks until that has been accomplished. Nevertheless, sometimes it happens that the presence of the foreign body is overlooked owing to its minuteness, and the symptoms are attributed to an attack of conjunctivitis. Nothing but the exercise of extreme care in the examination of the cornea can guard against a wrongful diagnosis of this nature, while it should also be borne in mind that conjunctivitis is not usually a monocular affection. The best method of examination for foreign bodies on the cornea is that of focal illumination, but in all cases of doubt the corneal surface should also be carefully inspected with an achromatic lens of high power.

The next class of cases to be considered in which a corneal lesion gives rise to pain is that in which photophobia is present. In children of the lower classes this photophobia usually results in blepharospasm, sometimes to such a pronounced degree as to render it impossible for the surgeon to examine the eyes without the aid of a general anæsthetic. But the symptoms in these cases are altogether out of proportion to the lesion which causes them. That is to say, when the cornea comes to be examined in the vast majority of instances nothing is to be found save a minute ulcer. Such lesion would seem to be a natural explanation of the phenomena. But there are some who profess to see a difficulty as to the causation of the photophobia. Indeed, it has even been said that photophobia is scarcely explicable physiologically. Let us inquire what the difficulty is. First, it is contended that the nerve-fibres of the cornea are not sensitive to light, a contention, I submit, which is not particularly concerned in this case. Furthermore, according to Nuel,[1] "the theory is advanced that in cases of keratitis accompanied by photophobia superficial inflammation of the sensory nerves of the cornea provokes hyperæsthesia of the optic nerve, or rather of its central termination, just as ordinary light gives rise to a painful sensation in the optic nerve apparatus." But against this theory it is necessary to bear in mind, as Nuel points out, that inflammation of the retina and optic nerve is not accompanied by pain. Thus it would seem that a difficulty has been raised where no difficulty exists. The explanation of photophobia appears to be simple enough; the sequence of events in its causation is, presumably, as follows. First, there is some loss by ulceration of the superficial corneal layers; this leads to the exposure of some filaments of the corneal plexus, and whenever these exposed filaments are subjected to any stimulation pain is caused. Probably it is not exposure to the light, but exposure to the air, which excites the phenomena of photophobia. An exact parallel in this connexion is to be found in the cases of irritable ulcers of the skin, the acute tenderness of which, as was pointed out by Hilton,[2] is due to nerve filaments lying exposed in some part of the ulcerated area. "Of course," he says, "it is quite clear that every ulcer must have nerves more or less exposed on the surface, but in the case of an irritable ulcer it seems probable that the sheath of the nerve is destroyed and that the end of the true nerve-fibre remains denuded and so causes the exquisitely sensitive and painful character of the ulcer." He describes some cases of irritable ulcer in which acute suffering was caused by merely blowing a breath of air upon them. Thus, in view of the delicate nerve-supply of the cornea, it is easy to comprehend that during a process of ulceration nerve filaments are so exposed as to give rise to acute pain whenever they are subjected to stimulation from air or other cause, and that absolute closure of the lids is essential to their protection under such circumstances. Without, however, discussing this matter further it may be noted that for the most part it is the superficial ulcers of the cornea in association with which photophobia is most apt to occur, leading to the inference that in deep ulcers thereof the destruction of nerve-tissue is more complete and the liability to pain and photophobia is correspondingly reduced. Mention may here be made of the fact that the blepharospasm and photophobia have been attributed to a conjunctival source. Having regard, however, to the nerve-supply of the conjunctiva this theory does not appear to have much to support it.

In the treatment of these cases of photophobia and blepharospasm a point of special moment is to encourage the child as much as possible to open the eyes voluntarily. Instinctively by many a little furtive movement a child with photophobia will be seen to make every effort to open the eyes at the earliest moment. The patient should therefore be placed in a cot or bed with the light coming from behind and a large shade should be provided to cover the forehead. Finding itself thus protected from the light the child soon begins to try to open the lids. Another point to bear in mind is that the patients are, for the most part, underfed, anæmic, or suffering from the effects of one of the exanthemata. A full nourishing diet, therefore, is an essential in the treatment, even to including a little port wine daily. Locally the eyes should be cleansed twice daily with a warm chinosol solution (1 in 4000), and atropine and cocaine drops should be at the same time instilled. Many drugs have been suggested for administration in these cases, but I have frequently found that a mixture of arsenic and quinine, in dosage according to age, acts like a charm. Under this treatment satisfactory results can always be obtained. I have never experienced the necessity of resorting to such heroic measures as may be exemplified by that of plunging the child, upside down, into a pail of cold water. In these days of scientific methods of treatment this can scarcely be commended, and how distressing it would be to a parent should she happen to witness the half-drowning of her child which the procedure practically involves. And what about the child who is thus subjected to a severe shock to the nervous system? Although the forcible and persistent closure of the lids in bad cases may indicate a serious condition of affairs there is usually, as I have already indicated, nothing further than a slight disturbance of the corneal epithelium. In other words, no apprehension need be felt that the cornea is in any danger of sloughing or that the ulceration present will proceed to perforation. Possibly the protecting warmth afforded by the closed lids largely assists in the maintenance of the nutrition of the cornea, and so prevents the ulceration from becoming progressive.

A structure so richly endowed with nerves as is the iris would naturally lead us to expect that whenever it became inflamed much pain would be experienced. The surprising fact, however, is that it does not always happen that an acute iritis is accompanied by pain. The pain, indeed, in a certain proportion of cases may be very slight or scarcely noticeable and yet a high degree of inflammation may be present. The conclusion, therefore, is obvious that the degree of pain present in a case of iritis is not always an indication of the severity of the attack. But another point must be borne in mind—namely, that the intimate connexion subsisting between the nerve-supply and the blood-supply of the iris and ciliary body establishes the fact that inflammation of the one may mean inflammation of the other. No rule, however, exists as to this; in other words, it is quite possible for the iritic inflammation to remain confined to that structure. When, on the other hand, the inflammation extends to and involves the ciliary body, then in addition to the increased ciliary injection of the globe another symptom becomes manifest—namely, a distinct tenderness of the globe on palpation. In an uncomplicated iritis the patient does not experience pain when the globe is touched; on the other hand, tenderness is always present when inflammation of the ciliary body has supervened.

In regard to the pain associated with iritis, the systemic cause of which is either syphilis or rheumatism, certain points may be noted. First, with reference to syphilis. In passing I may reiterate my belief that iritis dependent upon a syphilitic origin is becoming less and less frequent, for reasons which I have already advanced in a published paper.[3] The pain in syphilitic iritis is very variable, sometimes being scarcely noticeable, at other times being of the acutest description. Generally it is persistent—that is, it continues

# A Post-Graduate Lecture

ON

# OCULAR PAIN: ITS SIGNIFICANCE, VARIETIES, AND TREATMENT.

*Delivered at the West London Post-Graduate College on June 17th, 1901,*

By PERCY DUNN, F.R.C.S. Eng.,

OPHTHALMIC SURGEON TO THE WEST LONDON HOSPITAL; LECTURER ON OPHTHALMOLOGY AT THE WEST LONDON POST-GRADUATE COLLEGE.

GENTLEMEN,—The ideal subject for a post-graduate lecture, as I have observed here on a former occasion, is one which does not trench upon the province of the text-book; one which has for its basis practical facts easily lending themselves to assimilation by others; and one which does not travel beyond the limits of ordinary experience, thus avoiding the risk of making the discourse an academic display of knowledge possessing but little practical utility In endeavouring, then, to fulfil this ideal I shall occupy your time this afternoon with a practical, and what I hope will prove to be profitable, discussion upon the subject of "Ocular Pain: its Significance, Varieties, and Treatment."

First let us briefly consider the channel by means of which the human eye is endowed with common sensation. In this connexion it seems to be a marvellous fact that the sensory nerve-supply of the eye should be solely derived from a small branch of the nasal nerve which, as you know, arises from the first division of the fifth pair. I say marvellous, for surely it might have been the case that an organ of such importance as the eye would have been provided with a special sensory nerve for itself, or at all events that more than one small sensory branch would have been supplied to it to ensure against the contingency of interruption of the main source of supply. We can only conclude, however, that nature in making things as they are knew her own business. Presumably it was not needful to establish a complicated system of inter-communication with sensory branches, while, on the other hand, in the interests of the eye itself it was merely essential to combine its sensory supply with that of the adjoining nasal cavity. The influence of this connexion is mainly manifested when the eye is exposed suddenly to a brilliant light. Under ordinary circumstances the exposure of the eye to light is provided for by the contraction of the pupil, and such contraction is no doubt amply sufficient to protect the retina from harm. But let anyone turn his eyes upwards to the shining sun at noonday, and, as we know, the act is interrupted almost immediately by the occurrence of sneezing The explanation of this phenomenon I believe to be stimulation of the nerve-supply of the cornea. This seems to be reasonable, for while the retina is protected from harm by the contracted pupil the cornea would soon suffer were the exposure to the sun to be continued. The strong sensory impression caused by the sun's rays upon the corneal plexus is conveyed by the ciliary nerves to the central nucleus in the brain, with the result that the reflex act of sneezing is induced—an act with which is associated involuntary closure of the lids, and consequently the cessation of the exposure of the eyes to the source of irritation But this reflex act is also, and with perhaps greater interest, illustrated when a child with acute blepharospasm is placed under chloroform for the purpose of having the eyes examined. In these cases you will recall that as soon as unconsciousness is induced and the eyelids are retracted so as to expose the cornea not infrequently sneezing follows. Here, however, the light would be only relatively brilliant, inasmuch as the ordinary daylight in a room is sufficient to induce the sneezing. Nevertheless, it must be borne in mind that the child may not have had the eyes open for several days

I have alluded to the protection afforded the retina by the contraction of the pupil on the exposure of the eyes to light, and it is not without interest to recall how this contraction takes place. It is, of course, a reflex act; the optic nerve is stimulated by light and the pupil contracts by the impression being transmitted to the motor oculi. That is to say, the optic nerve, although a nerve of special sense, plays the part of one of common sensation. There cannot, however, be any sensory fibres, so-called, in the optic nerve, otherwise we would expect that papillitis and other inflammatory conditions of the nerve would be accompanied by pain. Thus it is of interest to note in this connexion that a nerve of special sense has been endowed with the characteristics of one of common sensation without possessing any sensory fibres How duly in accord, however, with ordinary physiological principles it would have been had this reflex act been dependent upon stimulation of the corneal plexus: the afferent and efferent paths of the nerve impulse would then be distinctly plain, and the result doubtless would be just as satisfactory as that which now obtains These observations might seem to suggest that nature had failed to be as wise as she might have been in regard to these pupillary arrangements Therefore, to pursue this matter further would be merely equivalent to indulging in unprofitable speculation.

Generally speaking, it may be said that pain is an invaluable symptom, and oftentimes the saving clause, in an eye which is the subject of disease Without it, as I shall proceed to show, patients would, indeed, fare badly. It teaches us many important lessons and provides us with many a clue to treatment. Take, for example, a case of acute glaucoma. It is not the loss of vision which compels the patients in these cases to seek advice; that is to them of secondary importance in comparison with the intense and agonising suffering with which the disease is commonly associated. Moreover, the surgeon knows that the greater the pain the more serious is the case and the greater the need for immediate interference. Thus the pain of a glaucomatous attack is the index of the peril to which the eye is subjected and marks out the line of treatment. Then, too, in the case of iritis, as long as the pain continues in these cases no improvement can be expected; on the other hand, the cessation of pain indicates the commencement of the retrocession of the disease and the progress towards recovery. Thus it is with most ocular affections—so much so that apart from diseases of the fundus, which are not painful, it may be said generally that the absence of pain in inflammatory conditions of the eye may be regarded as a favourable sign

So much, then, for the significance of ocular pain. I have now to consider its varieties, and I mean by this the different diseases of the eye in which pain is a prominent symptom Ocular pain varies in intensity and it varies with the disease, for example, very little pain occurs in connexion with conjunctival affections—a fact which is not difficult of explanation. The conjunctiva is only sparsely endowed with common sensation Moreover, it is a very distensile membrane which, when inflamed, is capable of being easily stretched Thus the sensory branches distributed to it are not compressed in any way and are consequently not irritated The sensory nerve-supply of the conjunctiva is derived almost entirely from the lacrymal branch of the ophthalmic division of the fifth, and it is not without significance to note that no direct communication appears to exist between the nerve supply of this membrane and that of the intraocular tissues. Perhaps we may assume that nature designedly kept the two sensory sources separate and distinct Reflect for a moment what the result would be were the ciliary nerves, after supplying the ciliary body and the iris, to be continued onwards into the conjunctiva Obviously upon every occasion that the conjunctiva was exposed to irritation and became inflamed the ciliary nerves could not fail to be involved in the disturbing or morbid process, as well as the structures to which they were distributed, thus exposing the eye and the vision to repeated and serious risks Again, the fact that this separate sensory nerve-supply exists is significant in view of the free communication which prevails between both the extra-ocular and intra-ocular lymphatic systems The lymph spaces of the conjunctiva freely communicate with those of the cornea, and it is doubtless through these lymph channels that solutions of atropine and other drugs, when instilled into the conjunctival sac, reach the anterior chamber. Furthermore, the blood-vessels of the conjunctiva freely anastomose with the ciliary arteries, thus establishing the union between the extra-ocular and intra-ocular vascular systems.

The next structure to be considered in connexion with ocular pain is the cornea. There is, perhaps, no other tissue in the body so richly endowed with common sensation as is this. The cornea has been well described as the object lens of the ocular camera The importance, therefore, of its

Edinburgh and East of Scotland Hospital in South Africa the mortality was 10·7 per cent. In considering mortality the age and condition of the patient must be borne in mind. Most of our patients were young adults, in whom the disease is less severe than in older people but more severe than in children, and many of them had suffered from considerable fatigue and privation not only before but even after they had been attacked. Our mortality (13·7 per cent.) is practically the same as that of the Metropolitan Asylums Board hospitals during 1900 and as that of the Worthing epidemic; it is almost double that of the Maidstone epidemic and the Johns Hopkins Hospital cases.

*Relapses.*—61 of our 262 patients suffered from relapse, but in 36 of these relapse arose either immediately or shortly after admission, the primary attack having occurred elsewhere. Subtracting these cases, there remain 25 out of 226 patients who relapsed in the hospital, an incidence of 11 per cent. Dr. Osler, in 829 cases at the Johns Hopkins Hospital, gives an incidence of 10 per cent.; Dr. Goodall and Dr. J. W. Washbourn, in 506 cases at the Eastern Fever Hospital, an incidence of 13 per cent.; Dr. Caiger and Dr. Goodall, in 611 cases, an incidence of 11·9 per cent. Dr. Rolleston, in an analysis of 244 cases at the Imperial Yeomanry Hospital at Pretoria, gives an incidence of 21 per cent. He, however, informs us that there are included among his cases a certain number of patients who had suffered from the primary attack elsewhere, which, we think, will account for the high incidence. At the Edinburgh and East of Scotland Hospital in South Africa in 150 cases the incidence was only 5·3 per cent. Possibly this low rate may be due to the early transfer of cases to other hospitals. It will thus be seen that our incidence of relapse corresponds with the average in England and America. We have no doubt that the too early removal of patients predisposes to relapse. 36 of our cases relapsed either immediately or shortly after admission, which we believe was due in many cases to too early removal and improper food on the journey. Of the 25 cases of relapse the shortest interval that elapsed between the end of the primary attack and the commencement of the relapse was 1 day; the longest interval was 31 days; the average being 10·8 days. In Dr. Poole's cases the longest interval was 24 days and the average 9 days. Of 53 cases of Murchison quoted by Dr. Osler the average interval was 11 days. In the Johns Hopkins Hospital cases the longest interval was 36 days, the average being 8·2 days. The shortest duration of the relapse was six days and the longest 23 days, the average duration being 13·5 days. In Murchison's cases the average was 15 days. Two of our cases suffered from two relapses, and one from three. We had no deaths among the 25 cases of relapse included in these statistics, which bears out the general experience of low mortality among relapses.

*Second attacks.*—In 12 of our 262 cases there was a history of a previous attack, an incidence of 4·5 per cent. There were actually only 99 cases in which it was definitely stated in the notes whether the patient had or had not suffered from a previous attack. This would give a much higher incidence of second attacks, but as the fact of a previous attack not having occurred might not have been noted we prefer to accept the percentage upon the whole of the cases. Dr. J. Dreschfeld in his article in Clifford Allbutt's "System of Medicine" states that at the Hamburg General Hospital, out of 2000 cases there were 14 in which there had been one previous attack and one case in which there had been two previous attacks, or an incidence of 0·75 per cent.; while Berg only found one second attack in 1624 cases, or an incidence of 0·06 per cent. Our incidence is therefore extremely high and this appears to correspond with the experience of others who have worked in South Africa. Brigade-Surgeon-Lieutenant-Colonel Alexander Crombie,[6] for instance, in the discussion upon Dr. Tooth's paper at the Clinical Society of London, states that of 150 officers who had returned invalided from South Africa for enteric fever 6 per cent. had suffered from previous attacks. The frequency of second attacks in South Africa appears to be chiefly due to the intensity and frequency of exposure to infection. In England individuals are probably not often exposed to infection. The fatigue and privation experienced in South Africa would also be a predisposing factor in rendering individuals liable to infection. One of our patients had suffered from two previous attacks and died during the third. The remaining patients recovered. The following is a short account of these cases.

No. 28.—The previous attack occurred seven years ago. The present attack was followed by relapse. The patient recovered.

No. 84.—The patient was an officer. The date of previous attack was not stated. The patient was admitted towards the termination of the attack, which was followed by empyema. The patient recovered.

No. 103.—The previous attack was 15 years ago. The present attack was attended by diarrhœa, spots, and enlargement of the spleen. The patient recovered.

No. 104.—The previous attack occurred when the patient was a child. The present attack was attended by enlargement of the spleen and by spots, and was complicated by otitis media. The patient recovered.

No. 160.—The patient was an officer. The previous attack occurred three or four years ago. The present attack lasted for 26 days and gave the serum reaction. The patient recovered.

No. 206.—The patient had had one previous attack as a schoolboy and another during the campaign. The present attack was very severe and the patient died.

No. 222.—The previous attack occurred one year ago. The present attack was attended by enlargement of the spleen and spots. The patient recovered.

No. 232.—The previous attack occurred in India 11 years ago. The present attack was mild. The patient recovered.

No. 243.—The previous attack occurred three years ago, and the patient had been inoculated three times just before the onset. The previous attack was due to the accidental ingestion of the typhoid bacillus in experimental work. The present attack was severe. The patient recovered.

No. 279.—The previous attack occurred in Egypt eight years ago. The present attack was accompanied by spots. The patient recovered.

No. 300.—The previous attack was in April, 1900. The patient was inoculated in January, 1900. The present attack was sharp and was accompanied by enlargement of the spleen, by diarrhœa, and by copious spots. The patient recovered.

No. 54.—The previous attack occurred four or five years ago. The present attack was followed by definite relapse The patient recovered.

*The influence of inoculation upon the course of the disease.*—In 211 of our cases it was definitely recorded whether the patient had been inoculated or not. 186 of these cases had not been inoculated, with 20 deaths, or a mortality of 10·7 per cent. 25 had been inoculated with 4 deaths, or a mortality of 16 per cent. The mortality was thus higher among the inoculated than among the non-inoculated. At the Portland Hospital 54 cases were inoculated with 4 deaths, and 178 not inoculated with 25 deaths. At the Imperial Yeomanry Hospital in Pretoria there were 27 cases inoculated with no deaths, and 115 cases not inoculated with 6 deaths. At the Scottish Hospital there were 15 inoculated with one death, and "about" 77 not inoculated with 10 deaths. At the Edinburgh and East of Scotland Hospital there were 18 cases inoculated with no deaths, but it is not definitely stated how many patients died among the non-inoculated. Adding together the cases at Deelfontein, Pretoria, the Scottish Hospital, and the Portland Hospital we find that there were in all 121 cases inoculated with nine deaths, a mortality of 7·4 per cent.; and 556 not inoculated with 61 deaths, a mortality of 10 9 per cent. In dealing with such small numbers the difference between 10 9 per cent. and 7·4 per cent. is too slight to point to any marked beneficial influence of inoculation upon the course of the disease. In our own series the mortality is greater among the inoculated than among the non-inoculated.

*The influence of inoculation upon the incidence of the disease.*—In our staff there were 44 nursing sisters; of these, 40 were inoculated and 2 contracted enteric fever, 4 were not inoculated and none contracted the disease. There were 10 ward-maids, all of whom were inoculated and 1 contracted enteric fever. There were 20 medical officers; of these, 9 were inoculated and 1 contracted enteric fever; 11 were not inoculated and none of these contracted the disease. There were 10 dressers, none of whom were inoculated and 4 contracted enteric fever. Taking the staff altogether there were 59 inoculated, of whom 4 contracted enteric fever, and there were 25 not inoculated, of whom 4 also contracted the disease. It will be noted that the 4 of the non-inoculated who contracted the disease came from throughout the day and night until relieved by local treatment. The most effectual treatment in the acute cases is local abstraction of blood by means of leeches, two of which may be applied to the temple on the affected side. For the most part it happens when the pain of a syphilitic iritis has been once relieved that there is no recurrence. Since in syphilitic iritis the inflammation is associated with the exudation of plastic lymph the pupil must be brought under the influence of atropine as quickly as possible. Unless this be done *there is great liability for the iris to be bound down by* posterior synechiæ to the anterior capsule of the lens, with the possibility of the eyes being irretrievably damaged. Of course, the patient must be placed at the same time upon a course of mercurial treatment.

---

[6] The Lancet, March 30th, 1901, p. 933

Next, in rheumatic iritis pain of marked degree is usually present, but it is mostly at night-time that the chief discomfort arises from this cause. These nocturnal exacerbations of pain are characteristic of iritis of rheumatic origin. During the day the patient is commonly almost free from pain. Again, the pain throughout is of a neuralgic character, thus *differing from the throbbing inflammatory* form, so to speak, associated with the intense vascularity of the globe observed in the syphilitic variety of the disease. The subsidence of the pain in rheumatic iritis is generally the first indication that the attack is passing off. Nevertheless, it is significant to remember that there may be frequent recurrences *of this* symptom. *The best* method of dealing locally with the pain in these cases is to apply dry heat. Nothing acts so well in this regard as the old-fashioned bran poultice. A large one is made, heated thoroughly in the oven, and placed over the affected eye. *The pain is soon relieved and the patient falls asleep with* the poultice in position. Leeching is not necessary, nor are sedative drugs in any form.

I now come to a class of cases in which the presence of pain is again of valuable import—namely, those cases in which the symptom is present in globes which have passed into an atrophic condition. In these cases tenderness on palpation and a dull aching pain are experienced in the lost eye—symptoms which, when accompanied by injection of the globe, definitely indicate that advanced degenerative changes, usually of the nature of ossification or calcification of the choroid, *have supervened*, and have involved such as is left of the ciliary region. The essential and imperative treatment under these circumstances is enucleation of the atrophied organ, the old belief being that such globes are a source of danger owing to their liability to set-up sympathetic ophthalmia in the fellow eye. I will not discuss here whether this belief accords with the latest ideas regarding the pathology of the disease beyond stating that in order to accept it as correct we should have to stretch our imagination far beyond the range of scientific facts and to take shelter behind *transcendental conjectures* quite at variance with scientific research. Nevertheless, apart from these considerations, no question can be raised as to the expediency of removing a lost eye which has become painful and injected. However, it will not always be found to be an easy matter to obtain the consent of elderly patients to undergo enucleation in these cases. The difficulty which they cannot understand is that an eye, or the remains of one, which has caused them no trouble for 20 years or more should ever require to be removed. In some instances it is apparent that an affection has been conceived for the damaged organ, and the refusal to part with it is based upon grounds of illogical sentiment.

I have briefly alluded to the pain associated with acute glaucoma. I *now propose* to discuss this more fully. *First*, how is the pain in glaucoma caused? Upon this point several details of interest arise for discussion. Perhaps the most natural reply to the question is that the pain is due to the stretching of the ocular tunics in consequence of the increase in tension. Presumably much of the pain may be explained in this way, but all of it cannot be so accounted for. Indeed, it is suggested that the raised tension gives rise to paralytic symptoms within the eye, thus accounting for the dilatation and immobility of the pupil and the *diminished* sensitiveness of the cornea, these symptoms being *attributed* to the compression of the ciliary nerves as they pass forward in the supra-choroidea. By some, on the other hand, it is believed that dilatation of the pupil depends upon vascular changes by which the circulation through the iris is wholly or partially arrested. That stretching of the sclera should be a painful process can be readily understood, in view of the nerve-supply of this structure. According to Baker, "the nerves of the sclera are derived from the ciliary nerves. Within the substance of the tunic they first lose their medullary sheaths; they break up into fine fibrillæ that appear to end like the nerves of the cornea in pointed filaments between the bundles of the connective tissue fibres." Another point is that the pain in glaucoma is proportional to the degree of vascularity present and the vascularity depends upon the tension, for the higher the tension the greater is the vascularity.

But it is impossible to believe that the intense suffering of an acute glaucomatous attack can merely or solely be due to stretching of the sclera; we must therefore look further afield for the solution of this problem. The most reasonable explanation appears to be the suggestion that much of the pain is due to the compression to which the ciliary processes are subjected during the progress of the attack. Again, in addition to their compression the ciliary processes, *owing to* the disturbance caused to the intra-ocular circulation, are distended with blood. Having regard, then, to the fact that next to the cornea the ciliary processes are the most sensitive part of the eye, it is not difficult to comprehend, under the conditions above mentioned, that they should be the seat of intense pain in the course of an attack of acute glaucoma. So far as the treatment of this serious disease is concerned the only method in which any confidence can be placed is that of iridectomy.

# TYPHOID FEVER IN SOUTH AFRICA.[1]

BY A. ELLIOT, M.A., M.D. EDIN., D.P.H. LOND.,
LATE SENIOR PHYSICIAN TO THE IMPERIAL YEOMANRY HOSPITAL, SOUTH AFRICA;

AND

J. W. WASHBOURN, C.M.G., M.D., F.R.C.P. LOND., F.R.C.S. ENG.,
PHYSICIAN TO GUY'S HOSPITAL; PHYSICIAN TO THE LONDON FEVER HOSPITAL; LATE CONSULTING PHYSICIAN TO THE IMPERIAL YEOMANRY HOSPITALS, DEELFONTEIN AND PRETORIA.

A LARGE number of the cases of typhoid fever admitted *into the Imperial Yeomanry Hospital at Deelfontein during* the year from March, 1900, to March, 1901, were convalescent on arrival, and the notes of others have been lost. We have, however, collected 262 cases, all of which were in the acute stage when in the hospital, and of which detailed notes were available. We have analysed these cases and have compared them with the following:—1. A series of cases which were admitted into the emergency hospital during the epidemic of enteric fever at Maidstone in the year 1897. These cases, 210 in all, have been carefully analysed by Dr. T. B. Poole.[2] 2. Statistics of 611 cases analysed by Dr. F. F. Caiger and Dr. E. W. Goodall.[3] 3. An analysis by Dr. W. Osler[4] of 829 cases treated in the Johns Hopkins Hospital during the years 1889 to 1899. 4. Statistics of 506 cases at the Eastern Fever Hospital during the years 1892–1894.[5] 5. Other accounts of typhoid fever during the campaign by Dr. H. H. Tooth, Dr. H. D. Rolleston, and Dr. F. D. Boyd. Our chief object has been to point out the main features of the typhoid fever occurring in South Africa and to ascertain whether it differs from that met with in England and America. At the same time we have considered the influence of inoculation upon the course and *the incidence of the disease, and* we have given a brief account of a few cases of special interest.

*Mortality*.—There were 36 deaths in our 262 cases, or a mortality of 13·7 per cent. At the Metropolitan Asylums Board Hospitals in 15,632 cases during the years from 1871 to 1900 the mortality was 18·44 per cent., while in 1900 the mortality was 14·09 per cent. In the Worthing epidemic in 1894 there were 2257 cases, with a mortality of 13 per cent. During the Maidstone epidemic 1847 cases were notified, with a mortality of 7·14 per cent. Dr. Osler in his text-book gives a mortality of 11·2 per cent. at the Montreal Hospital for 20 years and at the Johns Hopkins Hospital a mortality of 7·5 per cent. in the 829 cases analysed. At the

[5] Quoted in Goodall and Washbourn's "Manual of Infectious Diseases."

the parotitis was double and suppurative; the patient died. The other 2 cases were unilateral, one being suppurative and the other non-suppurative; both recovered.

*Pharyngo tonsillitis.*—There were 10 cases, an incidence of 3·05 per cent. In some of the cases there was exudation upon the tonsils of a follicular character.

*Abscesses.*—In 1 case two small abscesses developed, one in the right inguinal region and the other in the peri-anal tissue.

*Gangrene of the skin.*—In 1 case local necrosis of about the size of a florin occurred in two places—on the anterior surface of the right thigh and over the right tibia. The patient recovered.

*Appendicitis.*—In 2 cases enteric fever immediately followed a definite attack of appendicitis. In 1 case the patient recovered, but the other was fatal. Post mortem adhesions around an appendix distended with muco-pus were found in addition to the typhoid lesions. In another case, not included in our statistics, suppurative appendicitis followed an attack of enteric fever. Recovery ensued after operation. In the Edinburgh and East of Scotland Hospital a mild attack of appendicitis supervened in 1 case.

*Eruptions.*—In some of the cases the typhoid eruption was exceptionally profuse. In 2 cases a scarlatiniform eruption occurred which was attributed to an enema. In 2 cases there was a distinct *tache bleuâtre.* In 6 cases purpuric spots appeared on the skin, especially on the limbs; 3 of these cases were associated with spongy gums, and in 1 case there was frequent and profuse hæmorrhage.

*Secondary fever.*—Temporary rises of temperature occurred in a large number of cases. In many of these cases the fever appeared to be due to constipation.

*Otitis media.*—There were 4 cases, an incidence of 1·5 per cent.

*Pericarditis.*—There were 3 cases, an incidence of 1·1 per cent.

*Hepatitis.*—In 1 case there was hepatitis. The patient had a great and uniform enlargement of the liver during the pyrexial period. Abscess was suspected, but the enlargement subsided with the defervescence. The patient had not suffered from dysentery previously. Dr. Rolleston mentions a case of solitary liver abscess following enteric fever in a patient who had not previously suffered from dysentery and who recovered after operation. Dr. Osler reports a case of enlargement of the liver which subsided and ended in recovery.

*Jaundice.*—This occurred in only 1 case and was associated with fatal pneumonia.

*Orchitis.*—There were no cases of orchitis.

*Dysentery.*—There were 21 cases of dysentery occurring either during the attack of enteric fever or shortly before or after it. In 6 of these cases the dysentery preceded the attack, and all of the patients recovered; in 4 cases the dysentery occurred during the attack, and 2 of the patients died; while in 11 cases the dysentery occurred during convalescence, and 4 of the patients died. It would thus appear that dysentery arising either during the attack or during convalescence is of serious signification, the mortality being 33·3 per cent.

*Malaria and rigors.*—In 11 cases definite rigors occurred during the attack. In 2 cases the malaria plasmodium was found, and probably was present in a third, the patients at the same time giving the serum reaction. Dr. Poole noticed rigors in 8 of his cases, an incidence of 3·8 per cent., and Dr. Osler has specially called attention to their occurrence. Omitting the definite malaria cases, our incidence was 3·05 per cent. The following is a history of the 11 cases:—

Case 1.—This was a severe and prolonged attack of enteric fever, the pyrexia lasting for nine weeks. During the fourth week there were daily rigors without apparent cause. The patient was attacked with phlebitis three weeks after the first rigor. The patient recovered.

Case 2.—This was a severe attack, the pyrexia lasting for 25 days. There were rigors on the sixth, seventh, and eighth days of the disease. Pneumonia developed nine days after the first rigor and phlebitis nine days later. This patient had had malaria before. The patient recovered.

Case 3.—The patient had been ill for several weeks before his admission and he died on the sixth day after admission. While in the hospital he had several rigors.

Case 4.—This was a severe attack, the fever lasting for four weeks. Rigors occurred on the last day of pyrexia and again on the fourth, seventh, and tenth days of convalescence. The patient recovered.

Case 5.—This was a severe attack, lasting for 63 days. Several rigors occurred during the attack without definite cause. The patient recovered.

Case 6.—This was a moderately severe attack, lasting for 27 days. Several rigors occurred nine days after phlebitis had developed. Nine days later the patient was attacked with otitis media. The patient recovered.

Case 7.—Rigors occurred during an ordinary attack without any definite cause. The patient recovered.

Case 8.—The patient died from fever at the end of 21 days. Several rigors occurred during the attack.

Case 9.—This was a mild attack, the fever lasting about 11 days. There were rigors on the last two days of pyrexia. Doubtful malaria parasites were found in the blood. The patient recovered.

Case 10.—This was a severe attack, the pyrexia lasting for 59 days. The patient had had several rigors, and malaria parasites were found in the blood. He had suffered previously from malaria on the West Coast of Africa.

Case 11.—The patient had been ill for some weeks before admission into the hospital, where he suffered from pyrexia for 18 days. Malaria parasites were found in the blood, and it gave the serum reaction. The patient recovered.

*Arthritis.*—There were 8 cases of arthritis, an incidence of 3·05 per cent. In 1 case there was effusion. The following is a short account of these 8 cases:—

Case 1.—On the third day of convalescence there was pain in the fingers, shoulders, and knees, without effusion and without rise of temperature. Similar pain recurred on the nineteenth day of convalescence.

Case 2.—There was pain in the hips and ankles occurring on the ninth day of convalescence; this subsided in a few days.

Case 3.—This was a severe attack of enteric fever with petechiæ and spongy gums, followed by a relapse. Pain occurred in the right elbow with effusion and redness. The temperature went up to 104·2° F. and there was slight fever for the next two days. The inflammation subsided in about a week.

Case 4.—On the fourteenth day of convalescence pain occurred in the left shoulder and arm, with slight pyrexia lasting for two or three days.

Case 5.—On the twelfth day of convalescence there was pain in the right arm, hand, and ankle, the temperature being 103° F. Pyrexia lasted for about six days. There was a similar attack a month later which lasted for seven days.

Case 6.—On the last few days of the pyrexial stage pains occurred in the knees and elbows, lasting for several days.

Case 7.—During the pyrexial stage pains occurred in the back, shoulder, and ankle and lasted for two or three days. This patient had had rheumatic fever before.

Case 8.—During convalescence rheumatic pains occurred in the right arm. This patient had previously suffered from rheumatic fever.

It will be observed that in the last two cases the patients had previously suffered from rheumatic fever, which was doubtless the cause of the arthritis. But in the others no other cause than the enteric fever could be ascertained. Most of them occurred during early convalescence. The arthritis may be compared to that arising in scarlet fever—a comparison which is supported by the occurrence of suppurative arthritis in a case of which we have only the notes of the post-mortem examination.

*Epistaxis.*—Epistaxis was very frequent during the early stage.

*Tender toes.*—There were a good many cases of tender toes, such as have been described by Dr. Handford. The toes were excessively tender, requiring a cradle to keep off the pressure of the bed-clothes. There was no swelling and they all recovered.

*Conclusions.*—The conclusions which we draw from the analysis of these cases is that the type of typhoid fever met with in South Africa does not differ in any essential respects from that met with in England and America. The mortality and the incidence of complications are much the same as in the variations which are met with elsewhere. The only complication which appears to be specially prominent is phlebitis, which occurred in 5·6 per cent. of our cases. This was not very much higher than in Dr. Poole's cases at Maidstone, and in Dr. Caiger and Dr. Goodall's cases at the Metropolitan Asylums Board hospitals, which were 3·8 per cent. and 3·4 per cent. respectively. We do not feel that inoculation has any marked influence either in preventing or in modifying the disease.

among the dressers who were younger than the rest of the staff. At the Irish Hospital, quoted by Professor A. E. Wright, 64 of the staff were inoculated and 2 contracted enteric fever; 4 were not inoculated and none of these contracted it. At the Imperial Yeomanry Hospital, Pretoria, 35 persons were inoculated and 6 contracted enteric fever; 115 were not inoculated and 16 contracted the disease. At the Portland Hospital 28 were inoculated and 7 contracted enteric fever, 13 were not inoculated and 3 contracted the disease. At the Edinburgh and East of Scotland Hospital all—namely, 58—were inoculated and 9 contracted enteric fever. Taking all of these together, we find that there were 244 inoculated, with 28 cases, an incidence of 11·4 per cent., while there were 157 not inoculated, with 23 cases, an incidence of 14·6 per cent. The difference between the incidence of enteric fever amongst the inoculated and the non-inoculated is too small to be ascribed to any protective influence exerted by inoculation. We have not included the statistics of the Scottish Hospital, as the exact number of inoculated and non-inoculated is not definitely stated. The not infrequent occurrence of second attacks of enteric fever renders us doubtful of the prospect of successful inoculation in the future. The considerable risks of contracting enteric fever incurred in hospital work during this campaign are well exemplified by the above figures. Of a total of 401 persons engaged in attending the sick, 51 suffered from the disease, an incidence of 12·7 per cent.

*Hæmorrhage.*—We have included under hæmorrhage only those cases in which several ounces of blood were passed. There were in all 16 cases, an incidence of 6·1 per cent. At the Imperial Yeomanry Hospital in Pretoria there was an incidence of 8·7 per cent.; in Dr. Osler's cases 6 per cent.; in Dr. Goodall and Dr. Washbourn's cases 7·9 per cent., in Dr. Caiger and Dr. Goodall's cases 8·6 per cent., and in the Maidstone cases 5·5 per cent. Our incidence appears thus to be about the average. Of our 16 cases 8 died, a mortality of 50 per cent., and five others were noted as being exceedingly severe cases. Dr. Rolleston states that of 21 cases at the Pretoria Hospital 16 died, a mortality of 76 per cent. It thus follows that in South Africa hæmorrhage in enteric fever is a symptom of grave signification. In England and America the mortality does not appear to be so high; in Dr. Poole's cases there were two deaths, a mortality of 20 per cent., and in Dr. Osler's cases the mortality was 10 per cent. In the majority of our cases—namely, in 13 out of 16—the patients suffered from diarrhœa.

*Phlebitis.*—There were 15 cases of phlebitis, an incidence of 5·6 per cent. At the Edinburgh and East of Scotland Hospital the incidence was 6 per cent. Lieutenant-Colonel Crombie states that 25 per cent. of his cases suffered from phlebitis, but this high incidence appears to be due to the fact that many of his cases were invalided home on account of the supervention of this complication—a circumstance which vitiates his statistics. In Dr. Poole's cases the incidence was 3·8 per cent., in Dr. Caiger and Dr. Goodall's cases 3·4 per cent., and in Dr. Osler's cases 1·9 per cent. It thus follows that the incidence of phlebitis in South Africa is greater than in England or America. In our cases the left leg was affected 10 times, the right leg 4 times, and both legs twice. The phlebitis ensued during convalescence 8 times, during the pyrexial stage of the primary attack 4 times, during a relapse twice, and in one case the date was not noted. When occurring during the pyrexial stage it was towards the end of that period, the earliest appearance being on the sixteenth day. The latest date of its appearance after the end of the pyrexial stage was 30 days. It is probable that some cases developed phlebitis after leaving the hospital, but of these we have no record.

*Pneumonia.*—There were 10 cases of pneumonia, an incidence of 3·05 per cent. In Dr. Caiger and Dr. Goodall's statistics the incidence was 3·2 per cent., in Dr. Osler's statistics it was apparently 2·05 per cent., at the Pretoria Hospital it was 2·2 per cent., and at the Edinburgh and East of Scotland Hospital it was 1·3 per cent. The incidence thus appears to be about the same as in other statistics. Of our 10 cases 5 died, a mortality of 50 per cent., and at the Pretoria Hospital there was a similar mortality—namely, 2 deaths out of 4 cases.

*Pleurisy.*—There were 10 cases of pleurisy, an incidence of 3·05 per cent. In one of these cases there was effusion, which resolved, and in another case an empyema developed which had to be operated upon. In the Maidstone epidemic the incidence of pleurisy was 2·2 per cent. and in Dr. Caiger and Dr. Goodall's cases it was 2·6 per cent.

*Bronchitis.*—Bronchitis was not a marked feature of the attack. In 8 cases it was sufficiently severe to be specially noted.

*Periostitis.*—There were 6 cases of periostitis, an incidence of 2·2 per cent. In the Maidstone cases the incidence was 5 per cent.; in Dr. Caiger and Dr. Goodall's cases it was 1·1 per cent. In 3 of the cases the tibia was affected, in 1 the femur, in 1 the index finger, and in 1 the transverse process of the atlas. They all occurred during convalescence, except 1 case which occurred at the end of the pyrexial stage. The case in which the atlas was affected was an interesting one. A painful swelling appeared in the parotid region, which was at first considered to be a parotitis. When opened by Mr. H. A. Ballance the transverse process of the atlas was felt to be bare. The patient made a good recovery.

*Condition of the bowels.*—Of the 234 cases in which the condition of the bowels is clearly stated in 100 there was constipation, in 84 diarrhœa, in 41 alternate constipation and diarrhœa, and in 9 the bowels were regular. It will thus be seen that in 42·7 per cent. cases there was constipation throughout the attack. Dr. Poole states that 50 per cent. of his patients at Maidstone suffered from constipation, and Dr. Osler in his analysis of 829 cases at the Johns Hopkins Hospital states that 34 per cent. suffered from constipation. In the Edinburgh and East of Scotland Hospital 37 per cent. suffered from constipation. From these figures it would appear that constipation, not only in South Africa, but also in England and America, is much more common than is usually imagined. In the severe cases diarrhœa was most frequent, and of 35 of our fatal cases there was diarrhœa in 29, constipation in 4, and alternating constipation and diarrhœa in 2.

*Perforation.*—There were 6 cases of perforation—an incidence of 2·2 per cent. Dr. Dreschfeld gives an incidence of from 2·5 per cent. to 3 per cent.; Dr. Caiger and Dr. Goodall, 4·9 per cent.; Dr. Goodall and Dr. Washbourn, 3·1 per cent.; Dr. Osler, 2·7 per cent.; and at the Edinburgh and East of Scotland Hospital the incidence was 2 per cent.

*Cardiac complications.*—In many cases the pulse was exceedingly rapid and the patient suffered from cardiac collapse out of proportion to the severity of the attack. We attributed these cases to previous fatigue. Dr. Rolleston calls attention to the rapidity of the heart occurring during convalescence in patients who have been over-fatigued before the attack. We have also noticed the same during convalescence.

*Convulsions.*—In 2 cases there were well-marked convulsions, one of which we attributed to the administration of strychnine.

CASE 1.—The patient died at the end of the second week of a severe attack. On the day preceding death there were pharyngeal spasm and retraction of the head. Nasal feeding, which was attempted, brought on general convulsions. No necropsy was made.

CASE 2.—The patient died on the fifteenth day of the attack. On the eighth day there were general convulsions with opisthotonos and trismus, which subsided under morphia and chloroform. He had been taking for the previous 36 hours five minims of solution of strychnine every four hours. We attributed the convulsions to the strychnine. (Dr. Osler has described cases of convulsions occurring during enteric fever.)

*Abdominal pain.*—In 15 cases a special note was made of the occurrence of abdominal pain during the attack. The pain was at some time so acute as to suggest perforation, and, indeed, in one case the abdomen was opened under this belief. The peritoneum was found to be perfectly healthy and the patient made a good recovery. Most of these cases appear to be simple colic. It is possible that in some of them there was slight peritonitis. Dr. Caiger and Dr. Goodall state that in 2·2 per cent. of the cases analysed by them the patients suffered from peritonitis without perforation.

*Bladder trouble.*—Difficulty in micturition was noted in 5 cases at a time when the mental condition of the patient was perfectly good and in some cases quite early in the disease. In 1 of the cases a catheter had to be used all through the attack and in 3 cases on several occasions. In 2 other cases there was distinct cystitis. This list does not include the cases in which retention occurred while the patient was unconscious.

*Parotitis.*—There were 3 cases of parotitis, an incidence of 1·1 per cent. Dr. Caiger and Dr. Goodall give an incidence of 0·6 per cent., Dr. Poole an incidence of 0·5 per cent., Dr. Osler an incidence of 1·4 per cent., and at the Pretoria Hospital the incidence was 1·1 per cent. In 1 of our cases

It was for a long time my impression that the advocates of the first view were correct, but circumstances have now convinced me to the contrary, and the appendix should be removed as soon as possible after the healing of the abscess. My faith in the value of the general statement that removal is unnecessary was shaken, in the first place, by the formation of a second abscess (some months after the first had been treated by me) in the case of a boy, aged 16 years. The first abscess was a large subacute one with much surrounding exudation, and the pus was already making its way through the abdominal wall when the abscess was incised. Relying on the prognosis which I had been taught was the correct one I had given his parents the assurance of his freedom from further trouble of the kind. Some time after this, when I was passing by the theatre of the hospital, a young female patient was being taken in for operation. As the expression of her face indicated acute abdominal mischief I made further inquiry and waited for the operation. She had had a perityphlitic abscess treated six months before in a large hospital. The appendix was now in a condition of acute inflammation, with sloughing, but contained no concretion. She had diffused septic peritonitis secondary to this state of the appendix and died some hours after the operation. A valuable life would probably have been saved had the appendix been removed in the quiet period.

The advisability of this course is well illustrated by the following case in which the necessity of removal of the appendix was carefully impressed on the parents.

CASE 1.—In April, 1901, I saw a boy with my friend Dr. A. A. Brockatt of Malvern. His illness had commenced four days before with pain in the abdomen and sickness, the pain not being of a very severe character or the vomiting urgent. He had a temperature of over 101° F. and did not look very ill, but his pulse was remarkably soft and compressible. The abdomen was much distended; there was some dulness in the flanks; it was tender on pressure, especially about the right iliac fossa, and did not move well with respiration. Next day there was rather less distension of the abdomen and the dulness was mostly on the right side, where fluctuation was detected. An incision through the abdominal wall at the most prominent part gave exit to brownish, very offensive pus. As the coils of intestine were recently adherent and the appendix was not easily found it was not deemed advisable to make a prolonged search. The parents were advised to have the appendix removed, but from some cause or other this was not done, and in June an acute abscess developed in the same situation. The surgeon who was called in to operate on June 11th removed the appendix and drained the abscess, but the operation was a difficult one and the illness which followed was prolonged and complicated by the formation of a fæcal fistula. The appendix was enlarged and dusky red; in it there was the scar of an old perforation. (I am indebted for these notes to Dr. W. O'Donnell who kindly wrote to me about the case.) Here a second attack of suppuration, which might have been prevented, followed within three months; the boy suffered most severely and ran great risk.

Even if the appendix does not induce a second attack of suppuration it may cause a renewal of attacks which have made the patient's life a burden at times and prevented his following his employment, as shown by the following accounts. In both the attacks recurred after the abscess healed and suppuration, localised and diffused, might have ensued.

CASE 2.—In 1899 I was asked to see a medical man who was suffering from appendicitis. He had had several attacks during the preceding 10 years, some of them severe, and they had interfered very much with his practice. There was a hard mass in the right iliac fossa which extended to about the mid-line. In this there was evidence of fluctuation, whilst the temperature and other symptoms also pointed unmistakably to abscess. He was removed to a surgical home and preparations were made for operation. But after the administration of the anæsthetic and incision through the skin it was noticed that the tension of the abscess was much less, and when examination of the rectum was made pus was found showing that the abscess had burst through the wall of the rectum. He was examined per rectum before the operation was commenced and beyond adhesion and softening of the wall there was nothing to show a tendency to perforate. The patient was sent back to bed and in three weeks he had recovered from the rectal discharge. A small abscess required incision in the line of the recent scar in front after his return home. He did not recover his strength very quickly and in a few months began to complain again of pain in the region of the appendix and at his request this was removed. The operation was an easy one, there being no adhesions. The appendix was the subject of a chronic catarrhal inflammation with some stricturing towards the proximal end. He has continued well since and resumed active practice.

CASE 3.—On Oct. 18th, 1901, I saw a clergyman, aged 43 years, with my friend, Dr. A. E. Godfrey, who gave the following history. At Christmas, 1897, he had an attack of appendicitis and was ill for six weeks. An abscess formed which discharged per rectum, the discharge continuing for from 10 to 14 days. A band could be felt crossing the lower part of the abdomen on palpation. In October, 1899, he had an attack of sharp pain in the abdomen which lasted for three days, for which he was obliged to keep his bed. In the summer of 1900 he was ill for some days and was ill again a few weeks after that. In February, July, and September (1901) he had other attacks, being ill for ten days on each occasion. He suffered from sudden pain in the right side of the abdomen and vomiting. In February the vomiting was severe, and in September the pain was most troublesome, lasting longer than usual. At the operation, on Oct. 26th, for removal of the appendix nothing could be seen of it when the peritoneum was opened. There was no undue resistance or fold to mark its position, and it was only on separating the cæcum from the peritoneum of the iliac fossa that its proximal end could be discovered. It ran inwards and was adherent to the rectum by its tip, whilst lying concealed in a bed of adhesions. It was somewhat difficult to separate, the adhesions being firm and vascular. After removal it was found to be sausage-shaped, elongated, and thickened, contained muco-pus, and showed a tight stricture near the proximal end, about half an inch in extent. It appeared rather tense and fluctuating and suggested the near approach of another attack. There was a strong adhesion of the omentum to the peritoneum in the iliac fossa. The operation was done after displacement of the rectus to one side; the result was most satisfactory. He is no longer afraid to eat ordinary articles of diet which previously so often caused pain. This patient had been dissuaded from undergoing operation before he consulted Dr. Godfrey.

It may be considered that if a fæcal concretion is found in the abscess cavity the removal of the appendix need not be so strongly urged. It must, however, be remembered that there may be more than one concretion in the appendix and all of them may not have escaped out of the ulcerated opening. Of the average number of concretions in an appendix we have, so far as I know, very little information. There is an opinion that as a rule there is only one; but Dr. A. E. Russell, our resident assistant physician, who is a very careful observer, informs me that it is not at all uncommon to meet with two or three. The difficulty in getting the patient well in Case 4 was explained ultimately in this manner; two concretions were removed from the abscess with the pus, but a third remained behind and caused repeated abscess.

CASE 4.—A labourer, aged 40 years, was transferred from a medical ward to my care on July 10th, 1899. It was noted that he had been taken ill on June 28th with abdominal pain and vomiting. There was also a history of attacks of pain in the side of the abdomen, which he called "stitch," for a period of four years. On admission a swelling was present in the right iliac fossa, evidently an abscess. At the operation an incision was made through the right rectus sheath and the muscle displaced inwards. The abscess extended up behind the cæcum and the ascending colon, being shut off by adhesions from the general peritoneal cavity. Two fæcal concretions were removed from the abscess cavity which was irrigated and drained. The appendix was not found. He had still a sinus when sent to a convalescent home on July 26th. He was re-admitted in September, 1899, and a stitch was removed; the sinus was also scraped. The sinus closed, but he was re-admitted in November with another abscess which was opened. He was again admitted on Feb. 2nd, 1900, for a sinus which had followed a recent abscess in the old situation. On Feb. 22nd the appendix was excised; it was adherent to the pelvic wall and was separated with some difficulty, its walls were much thickened and in some parts cicatrised, and it contained a fæcal concretion. The wound was closed without drainage and healed without suppuration.

# NOTE ON THE "BLOOD RELATIONSHIP" OF MAN AND THE ANTHROPOID APES.[1]

BY ALBERT S. F. GRÜNBAUM, M.A., M.D. CANTAB., M.R.C.P. LOND.,

ASSISTANT LECTURER IN PHYSIOLOGY AT UNIVERSITY COLLEGE, LIVERPOOL; ASSISTANT LECTURER AT THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE, AND ASSISTANT PHYSICIAN TO THE LIVERPOOL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

THE new biological test for blood, depending on the investigations of many workers but brought into prominence and practical use by the experiments of Friedenthal,[2] of Deutsch,[3] and of Uhlenhuth,[4] has been pursued with much vigour, in this country more especially by Nuttall.[5] Having had the good fortune to obtain considerable quantities of the blood of three anthropoid apes—viz., the gorilla, the orang, and the chimpanzee—I am able to add a few new and, I venture to think, interesting facts to those already recorded.

The following brief recapitulation of what is already known is rendered necessary by the newness of the subject. In a general way it may be said that the serum from an animal—e.g., a rabbit—which has been injected intraperitoneally several times with any given organic fluid will, if mixed in small quantity with a dilute solution of the fluid used for injection, produce a more or less marked precipitate. To such a serum has been given the name "anti-serum." Hence the serum from a rabbit that has been treated in this way with human blood which gives a precipitate with human blood may be, although somewhat paradoxically, called "human anti-serum."[6] Such a serum has, to use the term applied by Durham to agglutinating sera, a "special" although not a "specific" action. For instance, my "chimpanzee anti-serum" gave a *slight* but distinct turbidity after a few hours with horse blood.

Other observers have already pointed out that "human anti-serum" precipitates the lower-monkeys' blood to a slight extent. Adopting the general mode of application of the test, I find that "human anti-serum" gives a precipitate with all three species of anthropoid apes already named, and to me this precipitate is practically indistinguishable from that obtained with human blood either in quality or quantity. Occasionally it has seemed that the blood of the orang gave a more gelatinous precipitate as compared with the granular precipitate of the other bloods, but this may have been due to accidental circumstances. The granular precipitates from other bloods are also liable to become sticky when shaken up. But it is not only by the action of "human anti-serum" on anthropoid blood that this close relationship of the various bloods may be demonstrated. I have prepared gorilla, orang, and chimpanzee anti-serum. Tested in the way described they all react, not only with their own blood but with each of the others, *and also with human blood.* Here again, in the absence of definite standards, I am unable to assert that there is any difference of reaction amongst the many combinations of anti-serum and blood which can be made with the four above-mentioned bloods and sera.

I have not noticed any record of a microscopical application of this test applied in the same way as in serum diagnosis. By this method, using one drop of 1 per cent blood solution with one drop of anti-serum, a result is produced reminding one very much of the clumping of bacteria, and in this way, too, it is possible to differentiate human and anthropoid blood, because there is an earlier and more complete reaction when the anti-serum is used on its own blood. By suitable dilution also of the anti-serum it should be possible to improve the utility of the microscopical method. I hope that the question of a quantitative method will receive the attention of workers in this field.

Pressure of other work prevents any present further investigation on my part in this direction and induces me to record at this stage the few results already obtained.

Liverpool, November, 1901.

# ON THE ADVISABILITY OF REMOVING THE APPENDIX VERMIFORMIS AFTER SUPPURATION CAUSED BY APPENDICITIS.

BY WILLIAM H. BATTLE, F.R.C.S. ENG.,

SURGEON TO ST. THOMAS'S HOSPITAL.

FOR some time the question has occupied my attention as to whether the appendix vermiformis should be removed after suppuration has been caused by its disease—that is, in cases where for some reason or another it was not removed at the time operation for the evacuation of pus was performed. The opinions held which govern the treatment of the appendix in these cases are much opposed. The first is that if a patient has an abscess the result of appendicitis there is such a profound destruction of parts as a consequence that the surgeon need trouble no more about the case—when once the abscess is closed the patient is cured as the appendix is obliterated. This view I have found, in conversation with various members of the profession, is rather generally held at the present time.

By a statement in his admirable work on the diseases of the appendix vermiformis Dr. H. P. Hawkins lent some support to this view when he stated "that eight out of 38 cases of perityphlitic abscess had a history of previous attacks of non-suppurative appendicitis, and in three of them a concretion was found." He had only met with one instance of second perityphlitic abscess Quite recently a well-known surgeon, Sir W. Mitchell Banks, is reported to have said,[1] when taking part in a discussion on appendicitis: "As soon as the suppurative stage had been diagnosed the pus should be evacuated, when the appendix was practically destroyed, and such patients had no return of appendical trouble."

The second view held by some is exactly the opposite of the first and may be summarised as follows, that in every case of perityphlitic abscess the appendix should be removed at the time of the operation.

Mr. Rutherford Morison[2] has devised a method of operating which he has successfully practised on several occasions, by means of which he considers this should be done, and of which, he says, the mortality is small. It involves an extensive incision of the abdominal wall and even to surgeons of large hospital experience appears somewhat formidable, and if attempted by one of slight operative skill might prove rather disastrous, whilst one cannot regard it as free from great risk of subsequent hernia There is another thing against it, and it is this, that in pelvic cases it may not be possible to remove the appendix. The operation will not succeed in all cases

Again, other surgeons hold the opinion that whilst it is advisable to remove the appendix when the abscess is opened there are cases in which such a procedure would involve unnecessary risk to the patient. There are many conditions any one of which in a particular case may appear so important as to induce the operator to postpone the removal of the appendix. For instance, the patient may be to ill to permit such a prolongation of the operation as might be required, the appendix may be so placed that it cannot be found; it may be considered that removal would involve too rough manipulation of bowel already softened by inflammation, the adhesions being very firm; or some areas of healthy peritoneum might be opened to infection from the abscess cavity. My experience has been in favour of the opinion last mentioned and tells against the view of non-interference. There appears to be a want of unanimity regarding the necessity for getting rid of the appendix if it has not been excised at the first operation, but some cases described below strongly emphasise, to my mind, the advisability of doing so.

does form it should be subjected to operation, when, if the appendix has not been taken away, removal can be done through the old scar and the opening closed. I was able to do this for a girl, aged 14 years, admitted to St. Thomas's Hospital in 1901 for hernia after abscess. The appendix was in a condition of chronic catarrh.

Harley-street, W.

## IZAL IN THE TREATMENT OF PHTHISIS.

By F. W. TUNNICLIFFE, M.D., M.R.C.P. LOND.,
PROFESSOR OF MATERIA MEDICA AND PHARMACOLOGY IN KING'S COLLEGE, LONDON; ASSISTANT PHYSICIAN TO THE NORTH LONDON HOSPITAL FOR DISEASES OF THE CHEST AND THE VICTORIA HOSPITAL FOR CHILDREN.

AT the present time any treatment of consumption other than fresh air and forced feeding is apt to receive but scanty attention at the hands of the profession. The reasons for this paper are two-fold Firstly, I am convinced that the treatment of certain cases of phthisis by antiseptics is productive of excellent results; and, secondly, there can be no objection to the use of drugs in combination with general hygienic treatment. At a recent International Congress on Tuberculosis at Berlin the exact position of drugs was well defined by Professor Kobert. Speaking from the fulness of his experience at Görbersdorf he said: "The fact that we possess no specific remedy in phthisis is far from the same thing as not possessing any useful drug. We possess no specific climate in phthisis but many useful ones." Nowadays it seems also fashionable to lay the chief stress in phthisis upon those drugs which exert a beneficial influence upon the digestive functions, even those acting on the pulmonary secretions being regarded as of secondary importance. This is presumably with a view of increasing the stock of energy (using this term in the physical sense) at the patient's command. A little oil often saves a good deal of coal. Truly an increase in assimilated food means an increased intake of energy. The effort necessary to expectorate a lump of sticky phlegm uses up, however, many calories. By making the phlegm less, or less sticky, by the exhibition of a suitable antiseptic or expectorant, the effort could have been lessened and thus energy saved. In this latter case, even had less nourishment been taken previously, the balance of energy remaining with the patient after the effort might well be greater than the one accruing in the case of the richer in-take. That we can cure early cases of phthisis without the use of any drug at all is undoubtedly true, but such a cure must be regarded as a *tour de force*, and is neither more nor less interesting than the sole use by a microscopist of a microscope made by himself.

Experiments made upon the tubercle bacillus with izal[1] have shown that in appropriate quantities it renders this organism incapable of producing either local or general tuberculosis when injected into animals. There have been further numerous experiments showing its antiseptic action *in vitro*.[2] This, however, is not sufficient to justify the physician in prescribing it in phthisis. The probability of the usefulness of an antiseptic *in vivo* depends, as Bouchard[3] has shown, not only upon its antiseptic power but upon the relation of this to its toxicity—i.e., upon its "*equivalent toxique.*" The antiseptic power of izal is relatively high and its toxicity is relatively low. An exhaustive series of experiments[4] on the pharmacology of izal have shown that this substance in appropriate doses exerts no injurious action upon the higher animals. It has also been shown elsewhere that izal when introduced into the alimentary tract exerts there its specific antiseptic action and can be demonstrated in the fæces. It has been further shown that one of its paths of excretion is the pulmonary mucous membrane, and it was inferred that it would exert there its antiseptic action. These experiments fixed provisionally the dose of the pure izal medical oil at about 10 minims. The following observations must be regarded as the clinical adaptation of the above pharmacological facts.

The izal was administered to the patients in two forms simultaneously. Capsules containing from 2 to 10 minims of izal oil with about five minims of cod-liver oil were given by the mouth after meals twice a day. At first one capsule was given—i.e., five minims of izal oil after dinner and supper—the dose was then increased to three capsules a day, and so on. More than 15 minims of izal oil per diem, was, however, never given. At first some of the patients complained that they tasted the drug for some time after swallowing it, but this soon passed off. One day's pause in four was always allowed from the treatment. The patient was directed further to sleep with an izal lamp burning all night by the side of his bed. By this means he breathed during the night air charged with izal vapour. This is rendered possible by means of a special lamp which consists essentially of a night-light burning under a tray containing izal. In all cases the izal treatment was adopted in addition to the so-called hygienic treatment The patients were with a few exceptions the better-class out-patients of a London chest hospital. The observations extended over two summers and almost two winters. Patients having evening temperatures of over 100·5° F. were told to stay in bed, with the windows open, or to rest in the open air. They were all enjoined to take as much milk and digestible food as they could. In no case, however, was any form of morphia given or any expectorant or so-called gastric tonic. The shortest time during which a patient undergoing the izal treatment was kept under observation was 12 weeks. The cases will be divided into classes.

*The first class* was formed of early cases with a history of, and a tendency to, hæmorrhage, but without fever. The physical signs in these cases were confined to crepitations at one or both apices with increased expiratory and diminished inspiratory murmur. The symptoms complained of were dry hacking cough, scanty blood-stained phlegm, loss of flesh, and weakness. In these cases the pulse was usually rapid, from 80 to 120, and the individuals might be described as being of the vaso-motor type. Ten of these patients were treated. At the end of six months six, in whom only one apex was affected, had lost their cough, all expectoration, and had put on from six pounds to one stone. The only physical sign remaining in four of these six was a slightly diminished inspiratory murmur. In the other two cases the inspiratory murmur was still distinctly diminished in the area of lung corresponding to the original seat of the disease. In all six cases tubercle bacilli, originally present, disappeared from the sputum. Of the remaining four patients belonging to this category one, after four weeks, became the subject of a severe hæmoptysis and was treated in the usual manner for six weeks and then resumed the izal treatment. After four months one apex had cleared up but the other still showed marked catarrhal signs. His cough had improved and he had gained weight. He is still under treatment. The remaining three cases were unfortunately only observed for three months. During this time the patients gained weight and improved generally. The physical signs, although much less distinct, had not in this time disappeared. In two of these three cases, at the end of two months and six weeks respectively, the tubercle bacilli had disappeared.

If the effect of the treatment in the above class of case be reviewed it will be seen that izal had a distinct salutary influence on the progress of the arrest of the disease.

*The second class* of case treated was of a much severer type. It is always a matter of some difficulty to classify cases of phthisis at all as they differ so largely *inter se*. When, however, the effect of some new remedy is being investigated some attempt at classification must be made. The following 15 cases had these features in common: fever, troublesome cough with lumpy purulent expectoration, a considerable area of one or both lungs presenting the physical signs of consolidation, and, in some parts, softening. The microscopic examination of the sputum showed the presence of both tubercle bacilli and pyogenic micrococci. Added to these signs were the more or less marked general symptoms of consumption. These consisted of loss of flesh, night sweats, anorexia, and diarrhœa. This last symptom was with regard to this method of treatment of special interest. In no case, however, was pronounced excavation of lung tissue present and this feature distinguishes this class from the following one. The patients with fever were kept in bed, or at least were

In yet another case a concretion left in the appendix was found to have been the cause of repeated attacks of suppuration, two of which were not clearly localised and both were very dangerous. The recovery from the first attack without sinus, with an appendix left *in situ*, containing a fæcal concretion, over which ulceration and perforation had probably taken place, is especially worthy of notice. It should certainly have been removed, but the surgeon had no doubt good reasons for not prolonging the first operation, and his decision was justified by the recovery of the patient.

CASE 5.—A girl, aged 14 years, was admitted into Beatrice Ward of St. Thomas's Hospital on Dec. 21st, 1900. It was stated that she had had an operation for peritonitis in May of that year, that on recovery from this she was sent down to a Brighton convalescent home, where in July she had an abscess of the right side of the abdomen. She was taken ill again four days before admission to St. Thomas's Hospital with abdominal pains and vomiting. The pain had not been very severe nor was the vomiting distressing. The abdomen was not rigid or distended and moved well on respiration. She said that she had pain which she referred to the right side of the lower abdomen underneath the right rectus; this pain was increased on pressure and there was some rigidity of muscle induced by firm pressure. The pulse was good, the temperature was 100·2° F., the tongue was clean, and the bowels had acted after a dose of castor oil. There were two scars in the lower abdomen—one made at the first operation in the middle line below the umbilicus, the other in the right linea semilunaris. With such a history, and in spite of the slightness of her symptoms, I thought immediate operation indicated. About two hours after admission the appendix was removed through an incision to the inner side of the outer of the two scars, the rectus muscle being displaced inwards. On opening the peritoneum a quantity of thin pus of dirty yellow colour and fæcal odour escaped. There were no recent adhesions; the neighbourhood of the appendix was washed with saline sterilised water, and the abdomen was closed. The appendix, which was bound down with old adhesions, was somewhat difficult to find and to separate; it contained a fæcal concretion and over it there was a ragged ulcer communicating freely with the peritoneal cavity. The scar in the linea semilunaris gave way a week later and discharged a small quantity of offensive pus for about a week, otherwise convalescence was not retarded in any way.

If the concretion which first caused the outbreak of suppuration remains in the appendix it may be the cause of a fæcal sinus, as it was in the following case. It is rather interesting, however, to note that the ulceration had healed and the sinus did not lead directly into the appendix at the time of operation. Yet who can doubt that other attacks of inflammation and possibly suppuration would have followed escape of the concretion, had it been able to get away, when there was in addition such a definite stricture of the appendix near the opening into the cæcum? Should the concretion escape from the appendix but not come away with the pus it may cause the formation of a sinus which will not heal until the concretion is removed. Some years ago I operated on a pelvic abscess in a young girl and could not find the appendix or any cause for the abscess. A sinus formed in the lower part of the wound and persisted for some months. Thinking this was possibly due to a concretion which had been caught in the drainage track the sinus was carefully sounded. A concretion was struck, the urethral forceps were introduced, and with some difficulty it was extracted in fragments After this the sinus rapidly closed.

CASE 6.—A man, aged 22 years, a soldier, was admitted under my care into St Thomas's Hospital suffering from intestinal fistula on July 31st, 1899 He had had attacks of appendicitis in March and August, and later, in November of 1898, he had been landed at Port Said from a troopship and been treated in the Lady Strangford Hospital for abscess. The appendix was not found when the abscess was opened. The following day the dressings were saturated with fæces and pus A fortnight later he also passed pus by the rectum. Convalescence was retarded, but with the exception of the fistula he was in fair health when he left the care of Dr. E. Cuffey (to whom I am indebted for the notes). The discharge from the fistula was usually small in amount, but excess in diet or undue exercise was punished by a profuse discharge, yellow in colour A hard collar-like lump could be felt under the scar in the right iliac fossa, and to this the probe directly passed. The operation was not performed until other methods had been tried without benefit. The appendix contained a fæcal concretion, of about the size of a cherry-stone, situated about a quarter of an inch from the base, whilst to its proximal side there was a complete stricture. The wound was sutured in layers so as to remedy the weakness of the scar which showed itself as a result of the prolonged suppuration, and he made a rapid recovery, the abdominal wall being without weakness some months later.

When a fistula which is not fæcal persists it is most commonly the result of irritation from a ligature or suture, and removal of this by means of a scraper with subsequent packing of the wound will suffice to cure it. Here there is not necessarily disease of the appendix. In the following case the sinus persisted until the appendix had been removed. The sharp bend in it caused by the angle at which it was adherent to the abdominal wall produced the same effect as that of a stricture of its lumen.

CASE 7.—A carman, aged 22 years, was transferred from the care of Dr. Hector Mackenzie to my ward in St. Thomas's Hospital on March 1st, 1901, for a large abscess in the right side of the abdomen, in which situation the patient had complained of pain for a period of six weeks. The pain had not been sufficiently severe to prevent his doing his work, although it had been fairly continuous until a fortnight ago, when it became severe and he had rigors and vomiting. The swelling extended from the middle of the iliac fossa to the lower ribs and backwards into the loin. It was very tender and fluctuating. Incision was made in the lumbar region and a large amount of very offensive pus was evacuated. The cavity was washed out with saline fluid and a drainage-tube was inserted. He left the hospital well on March 20th excepting for a sinus in the lumbar region, from which there was little discharge He returned to have the sinus scraped in April, but little benefit resulted from this and he entered the ward for removal of the appendix on May 15th. The oblique incision with displacement of the rectus was used. The appendix was adherent to the abdominal wall about four inches above the anterior superior spine. The omentum was adherent in the iliac fossa. A bullet probe was passed to the point at which there was adhesion of the appendix, but did not penetrate the entire thickness of the wall. The adhesions were dense and required a long incision to deal with them, the lowermost linea transversa requiring separation. The appendix was thinned where adherent to the wall, the subject of chronic catarrh and bulbous in shape, curled up on itself. In order to remove it, it was divided near the cæcum, turned up, and dissected out. He had a good deal of vomiting after the operation and some stitches in the anterior part of the wound gave way, but he left on June 20th, having quite recovered.

It will be observed that the opening at the tip of the appendix had closed before it was removed. This was after the prolonged rest in bed and careful dieting. Few doubted who saw the appendix that indiscretion in diet or over-exertion would have brought on another attack of inflammation.

I think there is only one exception to the rule that the appendix should be excised in all cases after the patient has recovered from the suppuration, if it was not found possible or advisable to remove it when the abscess was opened. This exception is when the appendix has sloughed off and is lying free in the pus or comes away during the healing of the abscess—not a very common occurrence when the suppuration is localised, but I have found it. It has been pointed out that there is not infrequently more than one concretion and there is no way of proving the exact condition of things without removal of the appendix and examination of its interior. These concretions are not faceted like gall-stones, so that it is not possible to say from the examination of one whether others are left or not.

It may be held, I think, that the evacuation of pus from an appendix abscess may be safely done through the ordinary incision; that it is not necessary to complicate the operation by any procedure which increases the risk; and that the removal of the appendix at a second operation, when the parts are quiet, will give a better chance to the patient in many, if not most, of the cases than a removal unwisely attempted or persisted in at the first operation. The adhesions forming after the inflammation of the surface of the opposed coils of intestine are not necessarily numerous, strong, or vascular; indeed, it is a matter for surprise to find so little change in the normal condition of the parts in many cases.

The question of the formation of hernia after incision for appendix abscess is not now under consideration. If hernia the fact that it exerted practically no action upon the circulation.

*The fourth class* of case treated in the above manner is numerically small—it consists only of two patients. Each of these patients had a large foul cavity at the base of the left lung. It probably in both cases arose from a localised breaking-down after pneumonia. Both the patients gave a history of pneumonia over the area in question. The expectoration was greenish, abundant, and very offensive. No tubercle bacilli were found in it. In each case there was slight evening pyrexia (about 99·5°) and in one case peptonuria. In these two cases the izal was administered in three different ways—viz., by inhalation two or three times a day, by means of the izal lamp at night, and by the mouth. The patients were observed for six months and are still continuing the treatment. In both cases during this time a considerable improvement has taken place. At first the expectoration was somewhat increased in quantity, but almost immediately after the administration of the antiseptic it became less fœtid and the putrefactive organisms became less numerous. This was followed by an actual diminution in its quantity which has continued up to the present time. *Pari passu* with this [illegible]turn to a more healthy type and diminution in the quantity [illegible] the expectoration, an amelioration in the general con[illegible]tion took place. The slight fever disappeared, as did also, [illegible] the one case, the peptonuria.

Summarising the foregoing results it may be said that so long as the individual differences in cases of phthisis remain so manifold, so long must we greet any addition to our non-irritating antiseptics with thankfulness. Of the efficacy of carbonate of guaiacol in certain cases nobody with any experience of it can have any reasonable doubt. The expense, however, of a prolonged treatment with this drug in many cases absolutely contra-indicates it. In spite of many requests from the profession the makers have been unable to reduce materially its price. Some few years ago, in conjunction with Dr. T. H. Arnold Chaplin,[6] the author introduced guaiacolate of piperidine in phthisis, but this, although possessing certain advantages, is also necessarily relatively expensive. In izal we appear to have a cheap and efficacious drug. The best results are to be obtained with it in cases of active pulmonary tuberculosis and of old cavities with abundant fœtid expectoration. According to my experience it seems to exert a beneficial influence in cases in which diarrhœa is present, whether this be due merely to decomposition of the intestinal contents or to actual tuberculous lesion of the intestine. In those cases in which the bronchitic element is well marked it is, as was *a priori* to be expected, less useful.

# OBSERVATIONS ON THE NATURE AND TREATMENT OF PERNICIOUS ANÆMIA.[1]

BY ALEXANDER McPHEDRAN, M.B.,
PROFESSOR OF MEDICINE, UNIVERSITY OF TORONTO, CANADA.

MANY causes and conditions have been adduced to account for the occurrence of pernicious anæmia, but none of them is satisfactory—nothing definite is known as to the actual cause. This unknown factor is generally believed to be a toxin; on this theory only can the phenomena be accounted for. Among the English-speaking profession generally the toxin is looked upon as of gastro-intestinal origin and that it acts on the blood of the portal system especially, causing rapid hæmolysis, and that the other effects produced are secondary, developing in the course of the disease. Many German physicians, on the other hand, refer the disease to a toxin affecting hæmogenesis, as shown by the abundance of myeloblasts in the bone-marrow and in the blood, indicating a reversion to the embryonal type. It is probable that both views are in part correct; that not only blood destruction but blood formation has been affected by a common toxæmia resulting in the genesis of abnormal corpuscles and the rapid destruction of the less resistant ones. The blood formation is atypical, and therefore to be attributed to pathological irritation rather than to excessive physiological stimulation. The other changes met with, especially those in the spinal cord and peripheral nerves, are probably produced by the action of the same irritant, rather than as the result of the protracted anæmia. The irregular course of the disease, with its remissions and exacerbations, its irregular fever, the frequent disturbance of the mental condition, and the occurrence from time to time of vomiting and diarrhœa, all indicate a common toxic cause.

The fact that the general condition does not bear a definite relationship to the blood state goes to show that there is something else than the poverty in corpuscles on which it depends. This is well illustrated by the contrast between the condition of a miller who was able to do without difficulty all but the heaviest work of his mill and yet his blood had only 1,000,000 red corpuscles per cubic millimetre, and that of a physician with over 4,000,000 corpuscles whose case is given in detail under the head of treatment. In the case of a member of the Canadian House of Commons during the past year there have never been more than 3,500,000 red corpuscles per cubic millimetre, and yet he has not only regularly and with marked ability attended to his duties in the House but has also conducted a most vigorous election campaign without either exhaustion or detriment. It is to be noted that in these as in all cases during well-marked remissions the colour index is always near the normal, and that the corpuscles show less deformity and there are fewer nucleated ones among them.

That the condition is a toxæmia is further indicated by the early occurrence of marked weakness. This, in most cases, is the first symptom and it may be complained of a considerable time before the pallor is observed. It must therefore be independent of the anæmia to which, as already stated, it is not proportional. In 22 cases observed during the last three years with scarcely an exception the first deviation from health noticed was the weakness; pallor followed soon afterwards. It is to be observed, also, that the early occurrence of weakness, before, as a rule, any disturbance of the digestive tract is noted, does not support the theory that the toxin is of gastro-enteric origin or that the digestion tract is the site of infection, but rather indicates that the changes in it are secondary to the toxæmia. The disturbances of the stomach and bowels doubtless, however, increase the toxæmia and therefore aggravate the condition.

The ground for the opinion that the toxin is of gastro-enteric origin is the constancy with which disease or disturbance of the function of the digestive tract occurs. Few, if any, cases are met with in which there is not at some time a history of diarrhœa and vomiting. In my 22 cases diarrhœa and vomiting occurred practically in all of them at some period of the disease, usually early, but sometimes later. The post-mortem conditions, however, found in the relatively few cases examined do not afford much support to the theory, as in most of them all that has been found is atrophy of the gastric mucosa. Atrophy, however, occurs in gastric carcinoma and many other conditions which have shown no signs of pernicious anæmia, and then there is wanting evidence that the atrophy is not a late change in the disease. The only evidence of its early occurrence is the absence of free hydrochloric acid from the gastric secretion, but free hydrochloric acid is temporarily, and occasionally permanently, absent in many other conditions. During the remissions in pernicious anæmia the appetite and digestion are often quite vigorous and a full diet may be as well disposed of as in health. At such times there is every evidence of a secretion of hydrochloric acid. Even in malignant pyloric obstruction hydrochloric acid may be restored to the secretion after the condition has been relieved by gastro-enterostomy.

Of late much importance has been attached to the probability of infection of the stomach by secretion from diseased gums around decayed teeth.[2] There is no doubt that such unhealthy conditions of the mouth may cause gastric catarrh, but that is far from proving it, even indirectly, to be a cause of pernicious anæmia. It is a question whether decayed teeth and diseased gums are found to exist in pernicious anæmia in a greater proportion of cases than in other chronic exhausting diseases. There is such a vast army of people whose teeth are decayed and whose gums are unhealthy that it would require a marked connexion between the condition of the mouth and any constitutional disease to establish a relationship of cause and effect even in a remote degree. In my 22 cases I have notes of the condition of the mouth in 17: one or more teeth were told to stay in bed, except once a fortnight when they came to the hospital. When the afternoon temperature had remained below 100° for a week they were allowed to get up for the first part of the day, and if the temperature remained down subsequently, for the whole day. There was no difficulty in getting the patients to take their own temperatures and even to keep charts, so, fairly accurate information upon this subject was available. Three of these patients at the end of three months were practically unaffected by the administration of izal oil. Their temperature range was one degree lower than at the beginning. Two of them had gained weight. The remaining one had in this respect remained constant. The cough in all three was somewhat better, but the expectoration remained abundant, thick, and purulent, and the numbers of tubercle bacilli and pyogenic cocci remained, as far as one could tell, approximately constant. The physical signs in the lungs gave but little evidence that the areas of softening or crepitation were appreciably diminished. At the end of three months these patients were treated in a similar manner without izal, and seemed to make rather slower progress. One of them asked to be again put on izal, and this was done with somewhat the same result as before.

---

[6] Brit. Med. Jour., Jan. 16th, 1896.

[1] A paper read at the meeting of the Association of American Physicians, Washington, on May 1st, 1901.

[2] William Hunter: THE LANCET, Jan. 27th, 1900, p. 221.

The results of the treatment in the case of the 12 remaining patients of this class will now be considered. In six of these the mischief was confined to one lung. These patients were observed for periods varying from four to seven months. In three the evening temperature at the beginning of the treatment ranged from 102° to 101°, in two no higher temperature than 100·8° was observed. In the remaining one there was no complete record of the initial temperatures. When taken in the out-patient room (afternoon) the temperature was 101°. The pulse of these patients was about 110. They were all losing weight. Two had typical night sweats. One had diarrhœa. This last patient, as he presents an interesting feature, may be discussed first. At the end of four weeks his morning temperature was normal, and the evening temperature had been for a week under 100°. He had gained two pounds, his pulse in the out-patient room was 90, as against 110 on previous visits, and the diarrhœa had practically ceased. When he first came his diarrhœa, which had been bad for six weeks and had existed for five months, was a very prominent feature of the case. In some earlier experiments I made with izal I found this drug to be remarkably potent in controlling intestinal putrefaction. This was evidenced by the cessation under its influence of the diarrhœa in several cases of infantile diarrhœa in the summer. Directly after the administration of the drug a diminution of the ethereal sulphates in the urine took place.[5] In the phthisical patient mentioned above there was, when he first came under my care, a large excess in the quantity of ethereal sulphates in the urine. This lead to the conclusion that the diarrhœa was attended with, and probably was accentuated by, fœtid decomposition in the intestine. In addition to this, previous experience of the arrest of phthisical diarrhœa, probably dependent upon the presence of actual tuberculous lesions in the intestine, by guaiacol carbonate, led one to infer that izal would be beneficial in these cases. *A priori* izal should both inhibit putrefactive decomposition and exert its bactericidal action upon the tubercle bacillus *in situ*. The anticipations were fulfilled; after its administration the aromatic sulphates rapidly diminished and the diarrhœa and intestinal discomfort *pari passu* with them. It may here be remarked that unirritating antiseptics are often more efficacious in the treatment of phthisical diarrhœa than so-called astringents. This patient continued under observation for a further period of three months and steadily improved. At the end of this period his evening temperature had for a term of four weeks not exceeded 99°. His cough and expectoration were confined to the early morning. The signs in the lung showed that a small area corresponding to the original softening had become excavated, but that the lung in the immediate neighbourhood had become free from crepitation. There was thus every hope that the disease had become arrested. On two occasions towards the end of the period I failed to find tubercle bacilli in the sputum.

The remaining five cases were similar to the one described above except that the general symptoms were not so severe. The patients all gained weight, practically lost their fever, and regained their working capacity. The cough and expectoration greatly diminished and were practically confined to the early morning. The physical signs in the lung showed in each case amelioration; this consisted, as above, in the area of softening becoming limited and in the disappearance or diminution of the crepitations and the reappearance of a fuller inspiratory murmur over the area which was previously the seat of them.

Six cases still remain to be considered, essentially the same, except that both lungs were affected. In one of these cases the patient who was observed for five months remained practically *in statu quo*. The weight increased slightly (four pounds) and the temperature range diminished, as did also the night sweats from which he suffered, but the physical signs in the lung remained practically the same. The remaining five cases all underwent distinct improvement. With regard to general symptoms the remarks made above concerning the other cases apply to these. The softening in the lung became in each case limited and the physical signs in the area situated between the breaking-down lung tissue and the healthy lung became very much less, or entirely disappeared. So far as concerns the less profoundly affected, lung improvement was observed in several different degrees. In one case the catarrhal signs entirely disappeared from the apex of the slightly attacked lung and full normal breath-sounds took their place. In the other cases the restoration to the normal of the affected area was not so complete. One of these last set of patients had albuminuria (one-tenth Esbach), and it is interesting to note that although he took relatively large doses (10 minims per diem) of izal oil no increase in the albumin took place.

*The third class* of phthisical patients, treated in the above manner, were in an advanced but chronic state. They numbered 10 in all. The disease was of old standing; in some cases of many years. There were, generally speaking, a large cavity with smaller ones and considerable cirrhotic change. Abundant crepitation and loud râles were present over extensive areas. The expectoration was very abundant, but varied in character from time to time, frothiness being occasionally more and occasionally less marked. In these patients fever was very rarely present and when it existed it was very slight. They may be roughly defined as being the subjects of old tuberculous lung disease whose symptoms were mostly of the bronchitic or broncho-asthmatic type. The best subdivision of them is the considering apart of those in whom the increased resistance to the circulation through the lungs gave rise to more or less marked derangement of the general circulation. This was distinctly present in four cases and was evidenced by cardiac dilatation, œdema of the ankles, and, in addition to these signs, in two, by the presence of albumin in the urine. Besides the two methods of administering izal mentioned above in these cases a third was used. This consisted in either suspending the izal medical oil by means of paroleine and using it for inhalation in a modified spray apparatus, or simply placing a few drops of izal in an ordinary metal inhaler and directing the patient to wear this as often as possible.

In one of these 10 cases the patient did not seem able to get used to the taste of izal and it was, after four weeks, discontinued. In three other cases, although the condition of the patients improved, at the end of four months the physical signs in the lungs did not give any marked evidence of amelioration. In the remaining six cases the increase in weight was marked, from 7 to 14 pounds in five months. The expectoration was very much diminished and very much less purulent, the cough was less frequent and less severe. The physical signs in the lungs showed that during the treatment the pulmonary cavities secreted less. Further, the loud râles for the most part disappeared and the areas of crepitations became distinctly less extensive. With regard to the severity of the coughing fits it is of interest that this became less severe, apart from the diminished quantity of expectoration. A hyper-sensibility of the bronchioles is probably answerable for some of the severity of the coughing fits in this class of patient, apart from the stickiness of the secretion. This is generally treated by substances the active principles of which exert a paralysing action upon unstriped muscular tissue, such, for instance, as belladonna. Izal exerts a slight paralysing action both upon sensory nerve-endings and also upon motor nerve-endings supplying involuntary muscle. This property of it probably explains its beneficial action in the above regard. So far as concerns the treatment by izal the patients with circulatory trouble were not to be distinguished from the others. The article referred to above upon the pharmacology of izal established were both old men and one of them died in the following year from acute diarrhœa, the other two years later from senility. In the physician's case the serum had no apparent effect, nor had it in three other cases in which it was subsequently used. During June anti-streptococcic serum was used, five cubic centimetres being given every two or three days at first and later 10 cubic centimetres; in all 125 cubic centimetres were used. During this time the temperature varied from 99·2° to 100·6° F. Some time after beginning the use of serum, after each injection a free secretion of saliva occurred which was sometimes blood-stained. No apparent benefit followed the use of the serum. The patient spent the summer of 1900 under most favourable conditions, living out of doors all day and sleeping in a tent at night. During the remissions the appetite was good and his diet was highly nutritious. By September he was considerably better but still his blood only contained about 3,500,000 red corpuscles per cubic millimetre. In October, on my advice, he tried spermin (Poehl), 10 cubic centimetres being given in divided doses extending over 10 days. He soon began to improve and during November his blood contained 4,500,000 corpuscles per cubic millimetre and the hæmoglobin rose to 85 (Fleishl). He looked quite well and said he felt as well as ever; the corpuscles, however, showed considerable inequality in size and a few nucleated ones could be found. He resumed his practice in a quiet way, but soon found himself unequal to the work. He became depressed; his mental condition which had been affected early in his illness and was not completely restored even at his periods of greatest improvement, now became so much disturbed that he became difficult to nurse. He was confined to bed although the blood showed only moderate deterioration, and in January, 1901, he grew suddenly worse and died comatose.

---

[5] Neubauer und Vogel: Analyse des Harns, Wiesbaden, 1893, p. 13.

In more recent cases I have advised moderate purgation, with the object of removing infective material from the bowel. At the same time intestinal antiseptics have been given, and such general remedies as strychnine, arsenic, iron, bone-marrow, and the like. The results, however, have been no less disappointing than former experiences. Notwithstanding all the good work that has been done the cause and pathology of the disease are as yet quite unknown, and as to its effective treatment we are equally in the dark. No plan of management or treatment so far devised avails to cure the disease or even, in most cases at least, to alter its erratic course. Before the recovery can be considered complete the blood on histological examination must be found quite normal. A restoration of even the full complement of 5,000,000 red corpuscles per cubic millimetre is not sufficient, as that may occur in a prolonged and marked remission. Not a few of the cures reported have doubtless been remissions of this kind.

Toronto.

# FRIEDREICH'S ATAXIA.[1]

BY GUTHRIE RANKIN, M.D. GLASG., M.R.C.P. LOND.,
PHYSICIAN TO THE DREADNOUGHT HOSPITAL, GREENWICH, S.E.;
ASSISTANT PHYSICIAN TO THE ROYAL HOSPITAL FOR
CHILDREN AND WOMEN, WATERLOO-ROAD, S.E.

FRIEDREICH'S ataxia is a sufficiently rare disease to make a group of cases such as the following worthy of detailed record. The patients are three sisters, aged respectively 20 years, 18 years, and 11 years, who belong to a family of four, the remaining member being a boy, aged 16 years, whose general health is reported to be excellent, but who is afflicted with stammering of a pronounced degree. The only point of importance in connexion with the family history is that the parents are first cousins. So far as can be ascertained there is no reason to suspect alcoholism or syphilis in either father or mother.

CASE 1.—The eldest of these three girls (Fig. 1) came to the out-patient room at the Royal Hospital for Children and Women some time ago complaining of gradually increasing loss of power in her legs, on account of which she had latterly found it a matter of considerable difficulty to get upstairs. She had always been perfectly well in her general health, but at the age of 12 years she first observed that her legs were becoming feeble. There was no wasting of the limbs, no history of previous acute illness, and no sensory disturbance. She had several chronic sores on her feet to which she attributed her difficulty in locomotion and the feeling of weariness in her legs. This history led to an examination of the patient's feet, and their appearance at once suggested the nature of her malady and prompted inquiries as to the health of other members of her family. Both feet presented the characteristic deformity of Friedreich's disease, being foreshortened with abnormally high instep arch and acute extension of the phalanges on the metatarsal bones (Fig. 2). The sores she complained of were numerous; a few superficial, others deep, and with some of the features of perforating ulcer. The soles were tender to the touch, and partly because of this tenderness—wholly, as the patient thought—and partly also, no doubt, from the deformity and muscular debility, she was unable to walk across the floor on bare feet. The girl then explained that she required to wear specially made boots to enable her to get about at all, but that with them she could manage pretty well so long as she was not required to do much in the way of going upstairs. This point, which to the girl is one of the striking features of her case, is noteworthy as prominently emphasising the fact that the flexor muscles of the leg are those which become specially impaired in the early stages of the disease. Her gait is more reeling than ataxic in character. This is brought out if she is asked to turn sharply round, when it will be observed that her efforts at movement are attended by a certain amount of shakiness. She walks with her toes turned inwards and with her legs widely apart. Romberg's symptom is well marked and she complains of attacks of vertigo which are always liable to be induced by closing her eyes when she is in the erect position. Her knee-jerks are absent and the plantar reflexes, though not abolished, are feeble. There is loss of motor power in both legs, but especially in the left, which she is quite unable to raise from the ground against the opposition of the most moderate pressure. Her arms are slightly ataxic, but not yet to such an extent as to interfere with her daily duties. There is no nystagmus and her eye-movements are normal. The optic discs are healthy and the pupils are equal and react freely both to light and to accommodation. Her speech is unimpaired and she is mentally bright and active. A fine tremor is to be noted throughout her muscles whenever they are put into use, and this is specially observable in the face, where sustained muscular tension, such as that required by the upper lip when called upon to uncover the teeth and gums, brings about, not only tremor, but after a few moments clonic contractions of the levator labii superioris, orbicularis oris, and other small circum-oral muscles. There is nothing abnormal about any internal organ, but her menstruation is somewhat irregular as to periodicity and is scanty. She suffers from pronounced ichthyosis, so that the congenital imperfection is not limited to the spinal cord, but implicates the skin as well.

The facts of the case leave little doubt as to the diagnosis, but full confirmation is afforded by the condition of the patient's two sisters.

CASE 2.—The elder of the two, aged 18 years, at once attracts attention on entering the room by her apathetic and almost vacant expression. Her gait is more shuffling but less ataxic than her sister's, and her speech is slurring, deliberate, and produced by a voice almost wholly wanting in both animation and inflection. She, too, enjoyed perfect health till the age of 12 years and her first abnormal sign was (precisely like her sister's) a difficulty in getting upstairs from feebleness of her leg-muscles. On examination she is found to possess the same foot-deformity (Fig. 4) but without any plantar sores, the same absence of knee-jerks, and, in fact, a replica of the sister's symptoms, but with the important addition of a marked curvature of the upper part of her spine (Fig. 3). The loss of power in her legs is not yet so far advanced as in her sister's case, but, on the other hand, on extreme conjugate deviation the eyes manifest oscillating movements which are not sufficiently sustained to be dignified with the name of nystagmus, but are still nystagmoid in character and in all probability represent the early stage of that condition. In her case tremor on movement is a well-marked feature and on watching her attentively for a little while one observes occasional choreiform twitchings which seem to be confined to the right arm and face. Her skin is normal and there is no impairment of her general health or evidence of disease in any thoracic or abdominal organ.

---

[1] A clinical demonstration at the Medical Graduates' College and Polyclinic on July 2nd, 1901.

carious in 10 of these, but nearly all of them were too well cared for to be a possible source of infection of the stomach. In only four of these cases were the gums unhealthy, three of them being only slightly affected and the fourth only fairly severely. In none was there a purulent secretion. It is further to be observed that these cases were not more affected by stomatitis or gastro-intestinal disturbances than were those whose teeth and gums were perfectly healthy.

One case at present showing very grave symptoms of pernicious anæmia was under treatment two years for dilatation and prolapse of the stomach with marked disturbance of its function. The patient was then quite thin and anæmic, but the blood did not present the characters of pernicious anæmia and she made a very good recovery. Her present illness began during the past winter. There was a history of pernicious anæmia in the family of two of my cases One of them, a young man, whose death is just reported, had a brother who died from the same disease about four years ago. The history was typical, so that there can be no doubt as to the diagnosis. The other case is that of a lady about 70 years old. She had been ailing for nearly two years and presented the characteristic symptoms in a marked degree. Two of her brothers died a few years ago from a disease with similar symptoms and history.

Symptoms of the disease of the nervous system occurred in nine of the 22 cases. In most of them there were only slight feelings of numbness in the extremities, the hands chiefly. In the case of a physician to whom I shall presently refer, not only the numbness, but ataxia, was quite marked, and the mind was not quite vigorous and clear even during his remissions, in some of which he was almost well. In the case of a lady, aged 68 years, there was a sensation of extreme coldness in the hands that was distressingly painful at times. In her case numbness was also marked Severe neuralgia of the head in all parts, but usually affecting one side more than the other, was the form which the nerve symptoms took in a young woman. The pain could scarcely be relieved, until a remission of all the symptoms occurred when she recovered fair health for a time; a relapse followed and terminated fatally six months later. Of the 22 cases 16 were males, an unusually large proportion. They were from all walks in life, but none were subject to undue privation or burdened with excessive work or "carking" care. In no case was any apparent cause evident.

In estimating the value of the treatment in any disease it is necessary to take due account of its natural course. This is especially true of pernicious anæmia, the course of which is subject to such sudden and extreme changes. There are few diseases in which more marked remissions occur. It is not unusual for patients almost moribund to be about in a few days and to resume work in a few weeks This was the history in the case of a man who had been ailing for some months, and in April, 1900, was so prostrate that he could not be roused; blood-stained fluid flowed from his mouth saturating his pillow. Yet in a few days he was sitting up, and returned to his home within a week, a distance of 100 miles. *During the summer he considered himself* well and worked at his trade as a stonemason. He relapsed in the autumn and spent the winter in-doors with hopes of improving with the advent of the warm weather, but he grew worse rather suddenly and died in April, 1901. Another man, under my care at the same time, in his first attack two years before was so prostrate that his physician told him that he would not be able to return to his office for a year; but he was there in two weeks, and continued well, as he thought, for a year when he relapsed, failing steadily with the usual exacerbations and remissions, until he died six months later. Such cases as these show the inappropriateness of the name "progressive" pernicious anæmia The disease is *remittent* not *progressive* Many cases run a milder and more persistent course, but in these also remissions occur and from time to time give promise of recovery. As in the case of the Member of the House of Commons already referred to, the recovery may be almost complete and remain unchanged for a year or more, but examination of the blood always shows some characteristic deviations, and a relapse may be confidently expected sooner or later. This has been my experience with the 22 cases observed during the last three years *Of these 14 patients have died, four* are running the usual variable course, and the remaining four have not been heard from for some time.

Arsenic, since its introduction by Bramwell, has until recently been regarded as a specific in pernicious anæmia. As the natural history of the disease has become better understood confidence in it has gradually lessened until now many regard it as of little value. The only case of complete recovery which I have had was apparently due to its action.[3] The case was that of a patient who in 1889 presented all the characters of pernicious anæmia with acute symptoms. The red corpuscles were reduced to 750,000 per cubic millimetre and there was marked poikilocytosis with much variety in size. Histological examination of the blood was not then further made. He took arsenic very freely for three months causing considerable peripheral neuritis His recovery was complete and he has since remained well. In the light of my more recent experience I am inclined to doubt the diagnosis, although it is not apparent wherein the error lies. In none of my late cases has arsenic proved of any service. In many of them it soon caused gastric irritation and had to be discontinued

The general acceptance of the theory of gastro-intestinal toxæmia has led naturally to the use of various antiseptics Of these bi-chloride of mercury has been most generally used, both locally as a mouth-wash as well as internally. My experience with it unfortunately has not been satisfactory; no tangible good has resulted from its use. The use of other antiseptics as salol, resorcin, creasote, bismuth salicylate, and bismuth naphtholate has been equally ineffective. Should this plan of treatment after due trial prove unavailing it will go far to show that the theory of the origin of the disease from a gastro-intestinal toxin is incorrect.

With a view of supplying the blood with an artificial serum and stimulating lymphagogue action and excretion of toxin by the kidney I have given normal saline subcutaneously in a few cases. I first gave it to an old man in the Toronto General Hospital who was so prostrate as to be almost unconscious. After the first injection of a pint he roused up and remained much better. A pint was given every second day and on the alternate days the same amount was given by the rectum. The subcutaneous injection was so painful that on recovering his normal mental state he declined to continue its use and the saline enemata soon caused diarrhœa and had therefore to be stopped. He improved very much and left the hospital in very fair condition with over 3,500,000 corpuscles per cubic millimetre. He returned four months later in a relapse and died in a few days. In a few other cases improvement followed the subcutaneous saline and in one there was apparently a recovery, but he may have relapsed as he has not been heard of for some time It is, unfortunately, too painful for most people to endure. The rectal administration should be as effective, but it cannot be continued on account of the diarrhœa.

If, as Rumpf[4] has lately pointed out, there is, in addition to the hydræmic state of the blood, an excessive quantity of sodium chloride present, it would seem injudicious to add more water and chloride of sodium to blood already surcharged with these constituents. If, however, the solution stimulates the renal secretion its use may so increase elimination from the blood as more than to counter-balance the *evil effects* of the introduction of more chloride of sodium and water into the blood.

The use of various other sera is illustrated by the history of the case of the physician to whom I have already referred He was 60 years of age and practised in a neighbouring city Symptoms of weakness were noticed early in 1899 and pallor shortly afterwards. His teeth and gums were healthy but he suffered much from stomatitis, especially when his stomach was disturbed, as it was frequently. He could take arsenic only for a few days, as it caused nausea and vomiting, and normal saline by the bowel set up diarrhœa Bi-chloride of mercury was used for some time, both locally for the mouth and internally for the general toxic condition, without doing appreciable good. Bismuth salicylate and similar antiseptics were given from time to time for the diarrhœa which always recurred when the stomach was disturbed. His history was the usual one of mild exacerbations and remissions Plain horse serum was then given subcutaneously in the hope of stimulating lymphatic action, but the only effect was to produce a severe urticaria This was also the result of its use in three other cases Then anti-diphtheritic serum was used, two cubic centimetres being given every second day. Its use in two previous cases had been followed by gratifying results, doubtless *post hoc* rather than *propter hoc*. The patients of perfect health. It is of special importance to note that she has not yet reached the age at which both her elder sisters first began to droop, because it has become one of the recognised tendencies of the disease to manifest itself at the same age in members of the same family—so much so that one of the most favourable of all prognostic facts is the absence of symptoms after the age of incidence has been passed.

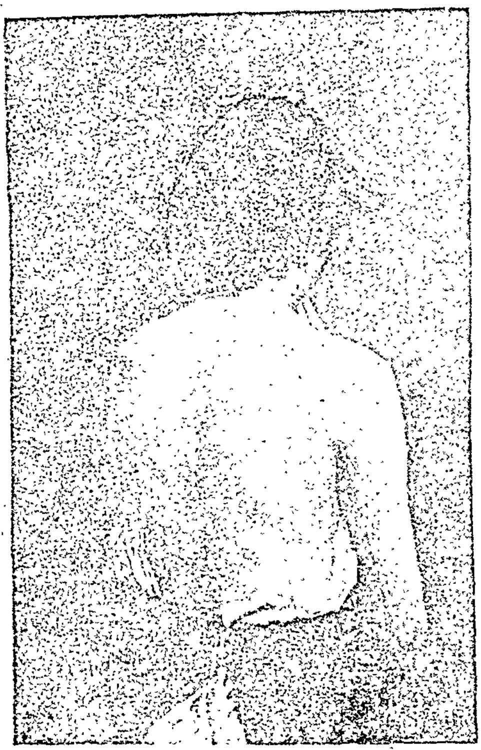
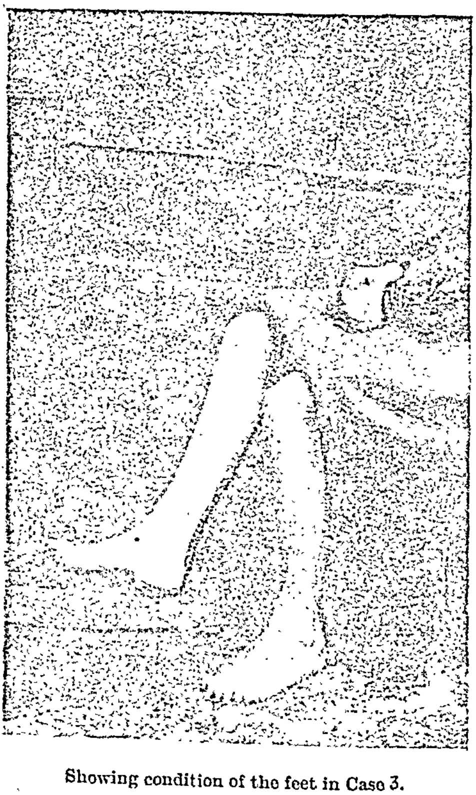
FIG. 5.



Showing condition of the back in Case 3.

FIG. 6.



Showing condition of the feet in Case 3.

Though the disease has not reached its full development in either of these girls the three cases taken together portray in unmistakeable colours the picture first painted by Friedreich. The absence of certain phenomena, such as well-marked nystagmus, pronounced ataxia of the upper arms, emotional instability, &c., is to be explained by the comparatively short time during which the disease has been in progress. It is, of all nerve disorders, one of the slowest. Many important symptoms, therefore, remain to declare themselves in process of time, and already in these present cases a certain amount of evidence is forthcoming that the advent of some of them will not be long delayed.

The photographs in the accompanying illustrations have not succeeded in bringing out as well as they might have done the deformities of the feet and back, but they illustrate clearly enough some abnormal features and have been taken with a view to future comparison. The attitude and shape of the feet are, in all three cases, already striking. There is no marked curvature of the spine to be seen when the back of the patient in Case 1 is examined, but the photograph fails altogether to portray the bend which is strikingly in evidence in Case 2, and only imperfectly reproduces the slighter, but still undoubted, curvature which the youngest girl (Case 3) presents.

Friedreich's ataxia is essentially a family, as distinguished from a hereditary, disease; it attacks several members of the same family or generation, isolated cases being comparatively rare. Obviously it can seldom be a directly hereditary disease, because in the vast majority of cases it is so far advanced before the marriageable age is reached that a matrimonial alliance is out of the question, not necessarily from actual sexual incapacity, but on account of the helplessness and crippling which have been already by that time produced. There is nothing definitely known as to the etiology of the disease beyond its dependence upon congenital conditions of the spinal cord. It has been variously ascribed to alcoholic excess in one or both parents, to syphilis, to parental consanguinity, and to preceding acute febrile disorders—such as measles or scarlet fever. It has also been said to occur with greatest frequency in families of unusual numerical strength. None of these causes are adequately sufficient to explain its occurrence. As regards syphilis, for instance, it is now accepted that it may be definitely excluded as a direct cause, though it may coincidentally exist. The speech defect by which the only son of this family is afflicted goes to confirm the supposition of an unstable inheritance so far as nerve tissues are concerned, and the ichthyotic skin of the eldest daughter (Case 1) further proves a congenital tendency to imperfect development. But no more can be said in favour of consanguinity as a cause than that weaknesses of tissue inheritance are more likely to be intensified in the children of parents who come of the same stock than in those whose ancestry is derived from parents born of entirely different strains.

Pathologically Friedreich's ataxia depends upon a sclerosis of the spinal cord which invades the posterior, lateral, and often, also, the anterior columns. In many cases the cord is smaller than normal, and this deficiency in size may involve the medulla and pons as well as the cord. Cases are recorded in which the cerebellum also has been found atrophied. The sclerosis of the posterior columns is usually complete throughout the whole length of the cord, and that of the lateral columns extends outwards and forwards so as to involve the direct cerebellar and the anterior pyramidal tracts. The cord lesion is thus much more extensive than in ordinary tabes which in many respects the disease so closely resembles. According to some authorities the sclerosis of Friedreich differs intrinsically from all other forms of sclerotic lesion in being purely neuroglial in character.

The two diseases with which Friedreich's ataxia is most liable to be confounded are locomotor ataxia and disseminated sclerosis. It may be distinguished from locomotor ataxia by the age of the patient, the existence of the disease in other members of the family, the altered speech, characteristic foot deformity, tendency to spinal curvature, muscular tremors, and choreiform twitchings, and by the absence of visceral crises, Argyll-Robertson pupils, lightning pains, and other sensory phenomena. If carefully observed the gait also will be found to differ in the two diseases; in tabes it is purely ataxic, whereas in Friedreich's ataxia it partakes of the cerebellar character as well, and thus

CASE 3.—The patient in this case—the youngest of the three girls—is 11 years of age and is supposed to be perfectly well, but on examination she presents three very suggestive symptoms. The great toe on each foot is hyper-extended and the extensor proprius pollicis stands out with undue prominence (Fig. 6); the knee-jerks, though not wholly absent, are so feeble that they can only be mildly elicited on reinforcement; and the small muscles of the face are distinctly tremulous when they are called upon to exert their full vigour. The girl is robust and energetic, she has experienced no muscular weakness, vertigo, or ataxia, and is, so far as she knows and to all superficial appearance, in the enjoyment

## REPORT ON LEGISLATION AND PRACTICE OF SANITATION AND HYGIENE IN ELEMENTARY EDUCATIONAL INSTITUTIONS OF SOME EUROPEAN COUNTRIES.

| Playground and drill-hall. | Building. | Schoolrooms— | | | | Seats and desks. | Latrines. | Physical training. | Hours of work. | Hygienic precautions. | Vaccination. | Number of elementary schools and special institutions. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | Area in metres per child. | Height in metres. | Ventilation. | Heating. | | | | | | | |
| | | | | | *France.—Paris (population 2,700,000).* | | | | | | | |
| Playgrounds: small, 700 sq. m. for 450 pupils, gravel or wood pavement; tree-planted. Drill-hall (*Préau*): 25 m. × 8 m. for 450 pupils; used as cloak-room, refectory, and playground, as well as for gymnastics and military drill. | From one-half to two-thirds of the primary municipal school buildings are modern. Some are in fairly open surroundings, others much enclosed. Neither basement nor roof-space is utilised. Corridors and staircases 1½ m. wide. Water on landings and in drill-halls. No bathrooms. | 8 m. × 7 m. for from 47 to 55 pupils. All rooms fully occupied and more space wanted. | 4 m. | Windows with moveable pane. Extraction opening in ceiling near chimney. One two-and-a-half inch opening between class-room and corridor. Outside ventilation: openings to spaces between ceiling and floor above. Air in rooms vitiated. Children pale, weak eyes, pimples, &c. No adequate provision for aeration during class. | Temperature 15° C. Iron or terra-cotta stoves which heat air taken from the room. Water-troughs found empty. | Either single, in pairs, or old-fashioned rows of desks. No support to the loins. All the same size in the same room. Part of the seat moveable. | Separate buildings. Open into portable receptacles or town drains; in the latter case self-flushing. Closets arranged for standing position. Arranged so as to be seen into—i.e., walls about 1½ m. high. One closet for 65 pupils; urinals in same proportion. | Daily physical exercises, besides gymnastics, boxing, fencing, and singing. | 30 per week including time for manual work, gymnastics, and singing. Intervals between classes. Hours: from 8 to 11 A.M. and from 1 to 4 P.M.—i.e., six hours daily except on Thursday, which is half-holiday. | Cleanliness of person and surroundings. Food either gratuitous or for small payment. Meat, 45 grammes; vegetables, 20 centilitres; soup, 30 centilitres. Summer colonies, some of which are permanent institutions, maintained by arrondissement. Pupils weighed and measured before and after summer outing. Good results. Medical visit every 15 days. | Vaccination and revaccination at 10 years obligatory. | 200 boys' schools; 200 girls' schools. Maternal schools for children from two to six years of age attached to several primary schools. Écoles enfantines intermediate between maternal and primary schools for children of both sexes from four to seven years of age. |
| | | | | | *Italy.—Milan (population 500,000).* | | | | | | | |
| Planted with trees, inclosed by a wall. Fine open spaces but rather crowded when in use—i.e., 36 × 26 m. for 700 pupils. Boys and girls have separate playgrounds. Drill-rooms 9 m. × 17 m. Central steam heat. | Old buildings rapidly giving place to new. The latter of modern construction, well placed and constructed in rectangular blocks or round three sides of a square. Spacious entrance halls, corridors, cloak rooms, &c. Corridors 3 m. wide, with taps and basins if the latter are not in the school-rooms. | 7 m. × 8 m. for from 50 to 60 pupils—i.e., 1 sq. m. per pupil. Generally not fully occupied. | 4 + | Windows 3 in number in each long side of the walls. Hopper lights. The air from the outside warmed by passing over encased radiator. Extraction opening near floor to roof 4 sq. dm. to 100 cubic m. | Temperature 13° C. Central steam or air. The former is more dependable. Condensed steam used again for boiler. The radiation apparatus in the rooms and corridors is arranged to heat the incoming air. | Isolated pairs of combined pattern on a ground frame. The seats lift on hinges and fold back; the top of the desk is immovable. Passage between rows of pairs. Four sizes of desks. | The latrines are self-flushing and they open into the town canalisation. They are syphoned and trapped. Sometimes with seat, sometimes without. One closet and one urinal to about 30 pupils. Special models for blind school and for school for defectives. | Special provisions for walking, running, jumping, and singing. Boys of the upper classes have gymnastics once or twice a week. | 22 hours per week. Upper classes: from 9.15 to 11.30 A.M., and from 12.30 to 2.45 P.M. Lower classes: from 9.30 to 11.30 A.M., and from 12.30 to 2.45 P.M. The pupils remain all day at school—i.e., do not go home at mid-day. | At the commencement of each scholastic year a medical examination of all pupils is made, and a report on a special form is presented to the authority. A monthly record is kept (1) of cases absented and re-admitted during the month; (2) of cases absented and not re-admitted; and (3) of those re-admitted from the previous month. In all cases the medical officer orders abstention and re-admission (for infectious diseases). Special provision and instructions for treatment of pediculosis. Cases of declared tuberculosis ex- | Vaccination and revaccination at from 10 to 12 years of age universal. Small-pox unknown in the schools. In the event of one case of small-pox all the class to be revaccinated except such as have been successfully revaccinated within five years. | 72 elementary schools (40,000 pupils). One school for deaf-mutes. One school for the blind. Two foundling schools. One school for defectives (*deficienti*). One school for stammerers. Special classes for backward children. Two *educatorii* or family schools for children (from four to 10 or 12 years of age) whose parents are at work. |

becomes a mixture of stamping and reeling. The resemblance to disseminated sclerosis is at first sight considerable In both affections there are nystagmus, a difficulty in speech, muscular tremor, and an abnormal gait, but on closer investigation it will be found that the nystagmus is more marked and developed at an earlier period of the disease in disseminated sclerosis than in Friedreich's ataxia; that the speech, though slurred and deliberate, is not so syllabic; that the muscular tremor is not rhythmical nor of the unmistakeable intentional type; and that the gait possesses none of the spastic element which characterises the disseminated case. Further and more distinctive points of differentiation are to be found in the facts that disseminated sclerosis is not a family disease; that it very rarely develops in persons under 20 years of age; that it is subject to periods of remission and exacerbation unknown in Friedreich's ataxia; and that the spinal reflexes are exaggerated and the optic discs frequently atrophied. The foot deformity and spinal curvature of Friedreich's disease are not present in disseminated sclerosis

The prognosis of the disease is, so far as now understood, hopeless. Its progress is usually slow, often lasting over a long period of years, but it is gradually a downhill one, and there is such eventual crippling that the patient is unable to do anything for himself—a helpless condition which sometimes is accentuated by the fact that the speech has become so slurred as to be wholly unintelligible No remedies have any apparent effect in arresting its course; it goes on steadily, however slowly, from bad to worse in spite of treatment. The most that can be done is to maintain the general health as thoroughly as possible, and this should be accomplished by means of good and abundant food, fresh air, suitable exercise, cod-liver oil, and general tonics. The constant current applied down the length of the spine may be of temporary value, and the use of a well-fitting rigid jacket will help to prevent the excessive development of spinal curvature.

hesham street, S.W.

# REPORT AND COMMENTARY ON SCHOOL SANITATION AND HYGIENE.

AS PROVIDED FOR IN THE FOLLOWING FIVE EUROPEAN COUNTRIES—VIZ., FRANCE REPRESENTED BY PARIS, ITALY BY MILAN AND FLORENCE, BELGIUM BY BRUSSELS, GERMANY BY STUTTGART, AND SWITZERLAND BY ZÜRICH.

BY STUART ALEXANDER TIDEY, M.D. LOND.

THE following report, drawn up during a rapid tour of inspection, represents the crystallisation in specific form of one element—viz., school hygiene, from a solution of general knowledge of continental methods of elementary education, acquired during 16 years' residence on the continent at intervals extending over a period of 30 years. To facilitate ready reference and comparison the reports are drawn up in tabular form and this was done in each case immediately after the visit of inspection was made. Thus confusion was avoided and the relative merits and defects were brought into strong relief.

The object of the reports is to afford an accurate appreciation of the work being done at various continental centres towards providing for the physical well-being of school-children educated at free elementary national or municipal schools. No consideration other than that of accuracy has been allowed to influence the compilation of results recorded. Reports on the same subject as treated in various countries must lead to comparisons, and should the comparisons drawn as a necessary part of this review come by any chance to the ken of those in charge of the institutions reviewed it is hoped that they will accept the conclusions as the result of sincere conviction based on a definite scheme of inspection. The selection of towns visited was made with a view to seeing a good, if possible the best, representative centre in each country. Whether this result has been accomplished or not it is impossible to say; possibly Berlin would have been a better representative centre than Stuttgart, and Le Havre than Paris; but accepting the centres visited as representative, the order of relative merit in which they stand in point of provision for elementary free education admits of no uncertain verdict except as to the claims of Belgium and Switzerland for the honour of first place. Together or separately, they excel all rivals in superlative excellence—Switzerland, represented by the town of Zurich, with its palatial school buildings arranged to meet every hygienic requirement, and Belgium, represented by Brussels, with its established structural excellence and highly-organised administrative programme; both marshalled by an energetic and progressive *personnel*, neither content with excellence but seeking perfection; Switzerland, more lavish in structural outlay; Belgium, if possible, more perfect in administrative organisation. Is there in either a determining element of superlative excellence or of essential defect to turn the scale? Yes; and reference to the respective reports will furnish the answer.

Under the head "Ventilation" will be found mentioned in the Swiss report opposite windows facing the lighting windows and opening into the corridor and extraction openings *near the floor* functioning in and out of class hours. In the Belgian report is no mention of opposite windows, and the extraction opening is *near the ceiling.* In relation to this structural difference there is no perceptible vitiation of the air at the end of the Swiss class, but at the end of the Belgian class there is perceptible vitiation of air. The Swiss engineer has provided a double extraction, and that for special function in winter near the floor. He argues thus. In winter the outside air passing over the radiator is heated and rises at once; descending as it cools, it reaches its destination at the level of the heads of the pupils, is not sufficiently heated by respiration to rise again, but finds its way to the extraction shaft by the low opening. In summer the entering air diffuses equally throughout the room, is warmed by respiration, and passes into the corridor or into the open air by the high opposite windows. The Belgian architect says: "The intake air is warmed by passage over the radiator, is breathed by the pupils, and then rises and finds its way by the high aperture to the extraction shaft." One of his premisses is false, by omission, and the conclusion falls to the ground. On this ground, involving as it does the most important hygienic principal—viz., that of proper aeration of the class-rooms—the palm of superiority must be awarded to the Swiss elementary school.

Next, and following close on the heels of the leaders, comes Italy, represented by Milan and glowing with the enthusiasm of the Risorgimento. Here, again, are fine elementary school buildings, well-designed to fulfil the demands of modern science and generously installed. Here also the *personnel* is proud of its schools and still striving to excel. Florence, too, far behind Milan in point of school buildings, has all the potential energy and will to convert her antiquated schools into educational palaces. To quote words recently used by Professor Del Greco: "Questi stabilimenti infelici sono destinati a sparire—a morto." ("These infelicitous buildings are destined to disappear—to death.") But while the Florentine bemoans the destitute circumstances of his seats of learning, he, nevertheless, makes the best use of them. One of the most infelicitous of the schools—viz., that of Salvino del Armato degli Armati—is a pattern of order and cleanliness Every attempt is made to do good work with bad material. What better warrant of future success? Then the institution for backward children, near Florence, is a model of excellence in point of administration and instruction, though housed in an ancient building

But to proceed, Germany, as represented by Stuttgart, comes next in order of merit. Here we see established scholastic success enjoying the dignity of recognised merit as the educational school of Europe, the buildings being of substantial structure and simple decorative design and fulfilling the established hygienic rubric. No indication is there of a keen progressive movement, but all is in order and everything established on a solid basis.

Next on the list under review comes France, represented by Paris. Many of the school buildings are of recent construction, but the best are not built to meet modern requirements of school hygiene. There is deficient width of corridors and staircases, the drill-halls have to subserve a variety of purposes, the basement and roof-space are not utilised, the ventilation is defective, and the system of heating is bad, the pupils are adapted to the desks instead

### REPORT ON LEGISLATION AND PRACTICE OF SANITATION AND HYGIENE IN ELEMENTARY EDUCATIONAL INSTITUTIONS OF SOME EUROPEAN COUNTRIES—(*Continued*).

### *Germany.—Stuttgart (population 170,000).*

| Playground and drill-hall. | Building. | Schoolrooms— | | | | Seats and desks. | Latrines. | Physical training. | Hours of work. | Hygienic precautions. | Vaccination. | Number of elementary schools and special institutions. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | Area in metres per child. | Height in metres. | Ventilation. | Heating. | | | | | | | |
| There is no playground in town schools. In the outskirts about 35 sq m. for 350 pupils. There are 10 large drill-halls in the town, with complete gymnastic apparatus, 26 m. × 14 m. generally used for 60 pupils at a time. Temperature 10° R. | There are some special and some adapted. Buildings either in town or outskirts, the latter being well placed. The corridors are 3 m. in breadth. There are no lobbies or cloak rooms, the hats, &c., being kept in the corridors or the class-rooms. In the basement are baths and heating furnaces. Roof-space for openings of hot air shafts and drying linen. | 1 sq. m. Rooms generally 9 m. × 7 m. The drawing and technical work-rooms are larger. | 4 m. | Windows with moveable pane. The air from outside is heated by stoves or by a central furnace. Extractors opening on the roof. | Temperature 15° R. in the class-rooms Central air or stoves with air-chambers and warm air-shafts. The latter open in the roof-space. Air moistened in the central chamber or in the room. | Generally rows of pairs. Some old-fashioned in rows of four each. Six sizes with the height of the pupil for which desk is adapted painted on each desk. Complete regulations for proportions of parts of combined desk-seats, for distance of desks from walls and width of space between them. The desk-seat measures about 1·25 m. long, 0·7 m. antero-posteriorly, and 1·2 m. in height at the back—i.e., the highest point. All angles of furniture are rounded. The "Rettich" pattern in general use. | In separate buildings. Each closet separated completely. All with seats. Opening leads direct into cess-pool which is ventilated by special furnace and high chimney shaft. Oil urinals for boys and girls. One latrine for 37 boys or 34 girls. | Gymnastics for older boys and girls form regular part of programme. Smaller children only walks, drills, and general attention to carriage. All have singing. | Range from 20 hours per week for the youngest to 32 for the oldest, including gymnastics. Hours from 8 A.M. to 11 A.M., and from 2 P.M. to 4 P.M. Wednesdays and Saturdays half-holidays. Intervals between all classes. | General regard to cleanliness. Baths in school not obligatory, but general. Table of infectious diseases in class-rooms. Table of first-aid in drill-halls. No regular medical visits. | Obligatory, "impfzwang." Re-vaccination obligatory between ages of 10 and 12. No case of small-pox had occurred in the kingdom of Wurtemberg for many years till 1899 when one case in an Italian student occurred, but did not spread. | 28 elementary free schools, 10 drill-halls, 10,429 pupils. One blind institute (private), and one deaf and dumb institute (private). Provision for backward children under consideration. Many kindergarten (private). Foundling teaching institute. |

### *Switzerland.—Zurich (population 158,000).*

| Playground and drill-hall. | Building. | Area in metres per child. | Height in metres. | Ventilation. | Heating. | Seats and desks. | Latrines. | Physical training. | Hours of work. | Hygienic precautions. | Vaccination. | Number of elementary schools and special institutions. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Ample tree-planted and gravelled spaces surrounded with iron railings. Boys and girls in the playground together Drill-halls 1000 square metres for 200 pupils, fitted with apparatus and weighing and measuring scales. | All are special; several quite modern. The entrance-halls, cloak-rooms, and corridors are spacious. There are large entertainment rooms, gymnasiums, and baths and douches (obligatory). The walls are washable to 1½ m. The floor-angle is rounded. The floors are of wood, asphalte, iron cement, linoleum, or cinolite. Four to five | 1 sq. m. + Class-rooms 10 m. × 6 m. to contain from 28 to 60 pupils. | 4 + | Hopper lights to the windows nearly the whole length of the outer wall. Hopper lights to the opposite corridor windows. Extractor near the floor with pipe opening into the roof-space. 4 sq. dm. per 100 cubic m. Cleaning flue to the chimney-stack also in the roof-space. | Temperature 14° C. Central—(1) water (expensive); (2) steam (best); (3) air (irregular). The radiators in the rooms, corridors, and latrines are arranged to heat the incoming air. | Combined seat and desk in pairs of varying patterns. The pairs are either isolated or in batches of five pairs on framework. Passages between longitudinal pairs of desks. | Automatic periodical flushing syphoned pedestals with seats opening into canalisation or clearing tank. One per class of 50 girls; one per two classes, or 100 boys, with urinals. This is found sufficient as the classes break up every hour. The lobbies contain washing apparatus. | Gymnastic instruction from 10 years of age onwards. Universal walks, drill, &c. Swimming, cross-bow, shooting, singing. Manual work carpentry, fitting, washing, cooking, modeling, and sewing. | Age from six to 14 years. Morning: 7 to 8 (summer), 8 to 9, 9 to 10, and 10 to 11. Afternoon: 2 to 3, 3 to 4, 4 to 5 (occasionally). A quarter of an hour interval between all classes. | Height and weight are taken and recorded twice a year. Holiday colonies. A medical visit every week in some schools. Vision tests for use by teachers in all rooms. A recommendation that hygiene and first aid be included as obligatory in normal schools. There is a table of first aid directions in the teachers' rooms. There are a hygrometer and a thermometer in the school-rooms. Daily soup-kitchens. | General, not obligatory. There was one case of small-pox two years ago. | 38 elementary schools (13,977 pupils). One blind and deaf-mute institute. Special classes for stammerers. Special classes for backward children. 30 kindergarten (1165 children), ages from four to six years, attached to the elementary schools. |

For elementary schools G Bini's combined chair and desk on ground frame Six sizes The desks slope Backs to support the loins The seat tips back on a hinge when the pupil stands The foot-rests are moveable for cleaning the floor The desks are in pairs | Pedestals without wooden seats or merely two slightly raised foot-pieces at the side of the aperture The latter leads direct into the cesspool some cesspools are ventilated One latrine per 50 pupils The new law requires syphons traps flushing cisterns and ventilation shafts but only one latrine for 50 pupils male or female | Boys half an hour daily and bigger boys gymnastics twice a week Girls; half an hour twice a week Project for swimming bath | 22 hours per week—arrive from 8 30 to 9 A M lessons from 9 to 10 30 A M rest from 10.30 to 11 A M lessons from 11 to 12 A M lunch from 12 A M to 1 P M work from 1 to 2 P M Girls do sewing &c in the afternoon and leave off at 2 30 The pupils do not go home at mid-day | Notices against spitting A table of contagious and infectious diseases in each director's room Suspected cases kept away Periodical cleanings and ventilation by open windows | Certificate in all cases After the lapse of 10 years re-vaccination In the event of one case of small pox all in the class who have not been vaccinated within five years to be revaccinated In the event of two cases in the class all are to be revaccinated | 38 elementary schools, two kindergarten, one school for the blind two schools for deaf mutes one institution for backward children imbeciles and epileptics and one institution for illegitimate children and foundlings |
| *Belgium —Brussels (population 200 000—town only)* | | | | | | | | | | | | |
| The play grounds about 1000 square metres paved with bricks sloping to the centre or gravelled and tree-planted They contain paved and glazed receptacles for excreta which are flushed periodically from an automatic tank Tout à l'Égout" | Mostly modern and made on the same model—viz. central covered hall (préau) 45 m × 15 m | 1 4 sq m | 4 5 m | Guillotine windows opening at top and bottom External openings behind radiator Extraction openings 40 cm × 45 cm near the ceiling for a room 7 × 8 × 4 5 m Shafts of these open into the roof space | Temperature 16° C Central steam or stoves The former with radiators placed in front of the air intake. The stoves in a similar position and in the corner diagonally opposite extraction aperture | Combined seat and desk designed by Mr Ramaekers after study of essentials and of recognised patterns The seats and desk lids are immoveable the former are small so as to facilitate entrance and exit Seven sizes Each isolated pair on platform raised about 10 cm from the ground | Periodical self flushing pedestals for sitting position head and feet visible One for 50 boys or 25 girls separate buildings | Physical exercises by teachers half an hour daily Bar bells dumb bells Indian clubs gymnastics walks swimming singing and manual work | 30 hours per week, including those for all physical exercises gymnastics and baths From 8 30 to 11 30 A M with a quarter of an hour interval and from 1 45 to 4 P M with a quarter of an hour interval From the age of six years onwards | Instruction to masters and pupils by medical officer Nourishment at midday when required Cod liver oil or poudre zootrophique A pamphlet is given to each member of the *personnel* on infectious diseases Dental department Bath and douche once a week Summer colonies Pamphlet of advice to mothers Medical visit every 10 days | Obligatory for admission to school | Eight boys schools eight girls schools and three boys and girls schools About 800 children in each school 13 000 in all Not more than 40 per class One school for backward and unruly children One school for the blind subsidised by the town One school for the deaf and dumb also subsidised Thirteen kindergarten of 200 each for children from three to six years of age Five new elementary schools projected School attendance not obligatory |

of the desks to the pupils, and the whole is less scrupulously clean than it might be. These defects cannot be all due to lack of means, for poor Florence can do much better in antiquated palaces. Some of the disadvantages of overcrowding might be mitigated easily by simple measures for regular aeration during class. The impression received is that defects exist because they are not realised. To the credit side, however, may be placed the excellent supply of midday food, the summer colonies, and the large provision for taking charge of young children from the early age of two years (nowhere else attempted) till they enter the primary school.

Such are the impressions received during a visit to representative elementary schools of five European countries. In conclusion, a word of grateful recognition should be said of the uniform courtesy extended in every case, alike by authorities and school *personnel*, to an unexpected and unknown visitor.

# Clinical Notes:

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### THREE CASES OF IMPERFORATE ANUS AND RECTUM.

By JAMES LAURIE, M.B., C.M. GLASG.,

*VISITING SURGEON TO THE GREENOCK INFIRMARY; ASSISTANT SURGEON TO THE THROAT, NOSE, AND EAR DEPARTMENT OF THE GREENOCK EYE INFIRMARY; AND SURGEON TO HIS MAJESTY'S PRISON, GREENOCK.*

THE relative infrequency of congenital defects of the rectum and anus prompts me to report the following cases which came under my observation and treatment in 1895. Keating, quoting Ball, says: "In a joint collection of 66,654 deliveries in Vienna and Dublin lying-in hospitals there were only three cases of imperforate rectum."

CASE 1.—I was called at 11 o'clock one night to see an infant (a female), aged 24 hours, and on my arrival at the house I found a midwife busy giving the child injections of soap-and-water, but "still she could get no passage." There was a well-formed anus, and on passing my finger three-quarters of an inch into it I found a very dense membrane occluding the passage. I opened it by a crucial incision, much to the relief of the child, and instructed the mother and the nurse how to keep it dilated by passing the finger, well-oiled, into the part. I saw the child some time afterwards and she was doing well.

CASE 2.—In the second case there was a very fine and delicate membrane closing the external aperture of the anus. The child had been born the evening before and no fæces had passed. The membrane was easily torn by a pair of dressing forceps and the mother was instructed to keep it dilated.

CASE 3.—I was sent for to see this child one forenoon and was informed by the nurse that the infant had been born 16 hours previously and had no anus. On examining the perineum there were a well-marked raphé and considerable bulging when the child strained or cried, but no indication of an anus. Under chloroform, which was administered by Dr. A. G. Newell, I made an incision from the centre of the raphé to the coccyx and felt the rectum bulging downwards. By a blunt dissection for an inch through cellular tissue I found the rectum ending in a blind pouch. Gently pulling it down I incised it by transfixion antero-posteriorly and sutured the ends of the skin. The sutures held. The child made a good recovery and had full control over his bowels.

The infants were all well nourished and were doing well when I heard of them last.

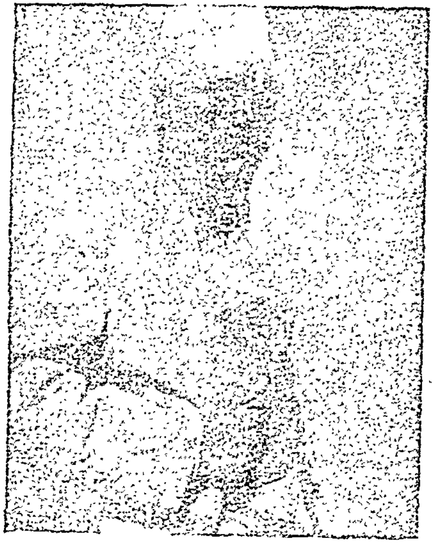
Greenock.

### NOTE ON A CASE OF FIBROMA IN THE MALE BREAST.

By A. WEBB JONES, F.R.C.S. ENG.

CONSIDERING how rarely one meets with new growths of the male breast I have thought the following case of pure fibroma perhaps worth recording.

The patient, an Egyptian soldier, aged 35 years, came to hospital complaining of a gradually increasing swelling of the left breast which he first noticed four months previously. Latterly he had also been troubled with slight pain. On examination the left breast was uniformly enlarged to about twice the size of the right. The outline stood out in marked contrast to the opposite side, but retained its general shape. On palpation the mass felt soft and elastic, but no indication of lobulation—as in a lipoma—could be obtained. It was freely moveable on the chest wall.



Showing patient before operation.

The breast was removed without difficulty by Thomas's incision. Microscopically the growth proved to be a pure fibroma.

Wadi Halfa.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

## PADDINGTON GREEN CHILDREN'S HOSPITAL.

### A CASE OF TUBERCULOUS PERITONITIS WITH OBSTRUCTION; LAPAROTOMY AND SHORT-CIRCUITING OF THE SMALL INTESTINE; RECOVERY.

(Under the care of Dr. G. A. SUTHERLAND and Mr. W. WATSON CHEYNE.)

A FEMALE child, aged three years, was admitted into the Paddington Green Children's Hospital in September, 1899. For three months the abdomen had been increasing in size and she had suffered from attacks of vomiting and constipation. There had never been diarrhœa or abdominal pain. In the family history there was nothing to be noted save that one brother had died from pulmonary phthisis. The child's previous health had been good. On admission she was found to be well nourished but markedly rachitic. The abdomen was much enlarged and tense, with dilated superficial veins. Fluctuation could be made out over the greater part, the fluid apparently being free in the peritoneal cavity. The liver was not enlarged and the spleen could not be felt. Deep palpation of the abdominal contents was impossible owing to the amount of distension present. Rectal examination showed the presence of ballooning. The heart and lungs presented no evidences of disease and the urine was small in amount, but otherwise normal. Mercurial inunction over the abdomen was ordered and a mixture of cod-liver

## REMARKS.

### FRANCE (Paris).

About one elementary school per 7000 inhabitants. The drill hall, small, and used for many purposes, is provided with water. The playgrounds are small and if on clay soil are paved with wooden blocks. The standard of construction of buildings is far inferior to that seen in Switzerland, Italy, and Germany, the general style of maintenance suffers equally by comparison. The rooms, constructed in the proportion of about 1 sq. m. per pupil, are often overcrowded. The height, which allows of a cubic capacity of 4 cubic m. per pupil, is sufficient, but owing to absence of adequate provision for ventilation the air in the rooms is sensibly vitiated. The stove heating maintains a temperature of 15° C., but the air, heated by circulation through an air chamber in the stove, is taken from the room itself, and the water troughs are sometimes found to be empty. Lighting is by gas, about nine over head (one and a half metres) burners with reflectors to each class room, besides one for blackboard. The seats and desks are of an inferior model and do not vary in size. The latrines are in separate buildings and are on the whole good but not sufficiently numerous. Considerable attention is given to physical training, object-lessons, and manual work. The three hours duration of classes is broken by an interval of a quarter of an hour both morning and afternoon. Hygienic precautions are not obvious, and the general physical condition of the children corresponds to defective ventilation. Judging from the full classes the maternal and "young children" schools are highly appreciated. Doubtless the conditions of a large city and pecuniary reasons account in a great measure for the relative inferiority of the Paris primary municipal schools, but such reasons cannot explain the defective aeration of the class rooms, a proper provision for which should rank *first* of all hygienic measures.

### ITALY (Milan).

One elementary school to about 7000 population. Some of the schools are attended by over 2000 pupils, boys and girls. Elementary school provision for about one-eleventh of the population. In modern schools the play grounds and drill halls are good, but the space is limited. The entrance halls, corridors, and lobbies are spacious. Lunch is taken in class rooms. In some buildings provision is made for keeping children up to 10 or 12 years of age till 6 P.M. (*Educatorii* or *Scuole famiglia*). The new buildings have basements about two metres high, well ventilated and serving to contain boilers of central heating apparatus, drains, and water pipes, also a lofty "solaio" or roof space. Here chimney stacks are fitted, in some cases with Albiati's fire-extinguishing and cleaning flue. The school rooms are adequately large and lofty and are well lighted, warmed (temperature 13° C.), and ventilated. The capacity is excessive both on account of the great height and generally because the rooms are not fully occupied. The steam heating is either at high pressure (one and a half atmospheres) or low pressure (one tenth atmosphere). The model of seats is not so good as elsewhere, but it is economical and it fulfils hygienic requirements. The latrines are generally good, clean, and in adequate numbers. Dr. di Cristoferis, the head of the Education Department, is very strong in his advocacy of simple exercises, such as walking, running, and singing, as compared with gymnastics proper. The lessons occupy from three and a half to four hours per day, with intervals between the classes. At the Scuola Poerio a tablespoonful of cod liver oil is given in addition to municipal rations to necessitous children. The special schools are exceptionally fine and well appointed buildings, with every modern sanitary installation including baths and douches. That for defective children is still unfinished, but is palatial in proportion and design. One wing only is occupied.

### ITALY (Florence).

One school to about 5000 population. The sites and buildings are generally ill adapted to their purposes, but every effort is being made to adapt present structures, often ancient and cramped in position, to modern requirements. The areas of playgrounds and drill halls are generally too small. The areas of schoolrooms vary considerably in different schools, in some there are passages between each pair of desks, in others not. Capacity is generally sufficient on account of the great height which provides against great heat in summer. Floors, pavement set in cement or varnished cement. The angles between the surfaces of the floors, walls, and ceilings are not rounded. Ventilation is not automatic but depends upon the teacher and therefore is uncertain. The latrines are not numerous enough and they are primitive but are kept clean. The chairs and desks are good with moveable seats; they are noisy when pupils sit down. Physical training is general in a limited degree. The hours of school work are from three and a half to four and there is little home-work. The teachers are well trained to watch the health of the pupils. Vaccination is universal and revaccination after 10 years. There is practically no small pox in Florence. Special institutions are all more modern and better found than ordinary elementary schools. Recent legislation is far in advance of practice in matters of school hygiene and sanitation.

### BELGIUM (Brussels).

11 boys' and 11 girls' elementary schools with a total attendance of 13 000—i.e., about a fifteenth of the population. Modern models accommodate 800. As school attendance is not obligatory children are removed at 11 or 12 years of age to work in factories. The playgrounds are large for the centre of a large city. The *préaux* and gymnasiums are spacious, clean, well ventilated and heated, and are admirably installed. The type of building, solid and permanent in structure, has stood the test of time as to suitability and is adopted as the established model. No unnecessary outlay or useless sacrifice of space betrays itself while no expense has been spared to attain hygienic and didactic excellence, and ample space is given to fulfil the most exacting hygienic requirements. The class rooms, lavatory, and gymnasium lead out of the *préau*. The entrance corridors two and a half metres wide are adorned with illustrations representing the results of alcoholism. The balconies around the *préau* are at the height of four and a half metres, into which the upper class rooms open. There are hat pegs in the *préau*. The latter is paved with ceramic tiles and the walls to two metres are lined with glazed tiles. There is a fine gymnasium with apparatus for Swedish and German exercises. The walls of the building are of brick, fully ventilated. The kindergarten are on the same model, but only one floor, three class rooms and one play room. The playroom is occupied constantly by each class in turn. The one sanitary defect which suggests itself is the insufficient provision for the extraction of vitiated air from the class room. The absence of corridors, except for the main entrance, is one of the characteristic features of the building. The boilers for central heating, baths, and douches are in the basement. The time allowed to each bath and douche is 10 minutes, and 150 baths are given per day in batches of 14 at a time, each pupil in a separate compartment. The roof space into which the extraction shafts open is clean and well ventilated. The schoolrooms afford ample area and capacity per pupil and are kept thoroughly clean. The seats and desks are of good pattern and are moveable for cleaning. The latrines are excellent, and the pedestals and lavatories are of English make. Physical exercises receive great attention. Hygienic measures of all kinds are firmly established, and I believe the dental department is a feature peculiar to Belgium. The kind of work is varied as far as possible from hour to hour. The special elementary institutions are good, and decidedly Brussels takes a foremost place among nations in its provision and administration of elementary educational institutions.

### GERMANY (Stuttgart).

One free school (elementary) to 6000 population. There is provision for one sixteenth of the population. The playgrounds are good, but not universal, they are surrounded by iron railings, gravelled, and tree planted. The drill halls are very fine; they are 10 in number and are used for higher as well as elementary schools. The buildings are fine but are not well provided with lobbies. The basements are provided with tile baths three metres by one metre for many pupils at a time or single tub baths, all are provided with shower baths. The central heating furnaces are in the basements. The outside air is filtered through canvas and is moistened in heating chambers and then conveyed to the class rooms in shafts which open into the roof space and which are cleaned by heavy brooms attached to ropes. The area and capacity of the school rooms are adequate but are somewhat less than at Zurich and Milan. There is artificial lighting only in the class rooms for drawing, carving, book binding, &c., and in the drill halls. The arc light with large reflector gives the best light, the arc light with reflection from the ceiling the second best, and the incandescent burners come third. Arc lights, however, require more attention and are not so dependable. The temperature in the class rooms is kept at 15° R. = 18.5° C. = 66° F., in the drill rooms at 10° R. = 12.4° C. = 54° F. The seats and desks are of varying patterns and are not all modern; they tilt on edge for sweeping the room and are not made in blocks of pairs but only in isolated pairs. The old and new of good patterns for sitting. The latrines are not of pedestal pattern; there are no water, no traps, and no syphons. Ventilation is by furnace and shafts. The school system here is established and does not betray the active progressive movement so noticeable in Switzerland and Italy.

### SWITZERLAND (Zürich).

One elementary school to about 4000 population. Some of the modern schools contain 1000 and 2000 pupils. Elementary school provision of all kinds for about one tenth of population. Special attention has been given to size and completeness of playgrounds and drill halls, which fulfil specified requirement in each case of three metres square per pupil. Drill halls warmed, ventilated, and fitted with gymnastic apparatus. The modern elementary school buildings fulfil requirements as to site, position, soil, surroundings, &c., and are palatial in design and proportion. They are generally from four-to-five storied buildings in addition to basement and roof space. The basement is used for boilers of central heating apparatus, sewage clearing tanks, sewage and water pipes, refectories for necessitous children, manual workshops, baths, douches, &c. The buildings contain special provision for kindergarten and class rooms for backward children and stammerers. The school rooms fulfil requirements as to area, height, cubic space, ventilation, heating, &c. Temperature always found about 14° C. Extraction flues work effectively both during and out of school hours and are of required area to change air about two and a half times per hour. The desks and seats of varying pattern all fulfil hygienic requirements, in some cases the pairs are in blocks five deep which are fixed on rollers and can be moved to either side for sweeping the room. They are made in four sizes. The lighting is by incandescent electric shade lamps, 1.5 metres above desk in the proportion of one lamp to nine pupils, and placed for light to fall on the pupils' left. It is suggested that arc lights (indirect lighting) would give more light and less shadow. The latrines are exceptionally good and no odour detectable. They are heated and the lobbies contain washing apparatus. Great attention is paid to physical training in class, drill room, playground, and on walks. The school hours are long but with intervals between all classes. Hygienic precautions include those against infectious disease as well as weighing, measuring, nutrition, bathing, holiday colonies, and general supervision. Vaccination is general but not obligatory, in which connexion it is interesting to note the occurrence of one case of small pox in spite of great hygienic precautions. In Zürich the maximum attention has been given to ordinary elementary schools as distinguished from special schools, which order is reversed in Italy.

The patient's condition did not, however, admit of the stomach being explored and he died within an hour.

*Necropsy.*—At the post-mortem examination an ulcer of the size of a threepenny-bit was found at the apex of the lesser curvature, near the cardiac end, and rather on the posterior surface. It was very high up and awkwardly placed, so that to introduce a tube would have proved a work of considerable difficulty. Except for the one ulcer the stomach was healthy.

CASE 2.—A man, aged 49 years, called Mr. Rendle up at idnight on account of severe abdominal pain. About n hour after a dinner of pork and stewed rhubarb he had egun to feel abdominal pain which had gradually increased ll now it was extreme, chiefly at the epigastrium. Morphia nd turpentine stupes relieved him and on the next day e seemed to be better, though still tender to the touch; is bowels, which had not acted on the morning of his ttack, were confined, not even flatus passing. On the following day this condition continued in spite of purgatives; he pain had practically vanished and Mr. Rendle concluded hat he had an internal obstruction to deal with. A surgical olleague saw the patient with him, agreed in the diagnosis, nd both advised removal to the hospital and an exploratory operation The patient and more particularly his iends all had a great horror of operation, and would only gree to his entering the hospital on condition that nothing hould be done until frequent enemata (which had been dministered at home, but not very effectively) had been ied; and most unfortunately these brought away a good deal of fæcal matter and he was able to pass flatus, his general condition being at first much improved. The improvement, however, was not maintained, and on the fifth day, as he was obviously losing ground, permission was obtained to operate. A ruptured appendix was found, ligatured, and removed, but the patient never rallied and died on the following day.

CASE 3.—A married woman, aged 41 years, was admitted into the South Devon and East Cornwall Hospital one evening on account of severe abdominal pain. She had suffered for years from indigestion off and on, but had been pretty well (for her) until two days previously. She then was seized shortly after breakfast with griping pains which lasted all day more or less; on the next day they still continued, but she was able to do her usual work and took her ordinary food. The bowels not having acted for two days she took half an ounce of castor oil at night, after which the pain just below the sternum became exceedingly acute, and continued so all night in spite of a copious relief of the bowels. She tried to get up on the following morning but had to return to bed. She was seen by a medical man, who put her on a diet of milk only, and sent her to the hospital in the evening. On admission she was obviously very ill; the temperature was 100 6° F. and kept rising, the pulse was 112, and the respirations were 24 and purely thoracic. The abdomen was distended and very tender, especially over the epigastrium; liver dulness was nearly absent. It seemed to all who saw her, looking at her symptoms and previous history, that a gastric ulcer was probably the cause of her trouble, and accordingly Mr. Rendle opened the abdomen in the middle line over that organ, but found it, as also the small bowel, save for flakes of recent lymph and free fluid in the peritoneal cavity, quite healthy. He then made a second opening through the right rectus and came down on a mass of omentum which was adherent somewhere near the appendix. This was transfixed and ligatured, when about an ounce of very fœtid pus was evacuated from deep down in the pelvis. The appendix could not be found for some time as it was bound tightly down by adhesions. The right ovary and tube, very swollen and œdematous, were removed, thus freeing the appendix and bringing it into full view. The patient's condition was now exceedingly grave and she seemed to be practically moribund. Dr. W. L. Pethybridge kindly transfused her with three pints of saline solution, and Dr. H W. Webber sutured the incision over the stomach while Mr. Rendle rapidly transfixed the appendix and meso-appendix with silk, tied it, and cut the appendix away close to the cæcum. He did not think it safe to spend even the little time necessary to fold in the edges of peritoneum, but put a Keith's glass tube deep down into the pelvis and closed the wound as rapidly as possible The patient made an uninterrupted recovery.

*Remarks by* MR. RENDLE.—The difficulties that attend the correct diagnosis of grave abdominal injuries are already sufficiently well known, but the above cases that have recently come under my care (during the illness of my senior) may be of interest as showing how even the most carefully formed opinion may prove to be in error. In each of these cases a wrong diagnosis was made as to the nature of the illness both by myself and by the colleagues who saw them with me, but I do not think that we were therefore to blame. Peritonitis was obviously present in each case and only the cause had to be determined. In Case 1 the onset seemed to be characteristic of a ruptured appendix, especially as there was an absolute denial of any previous indigestion or symptoms pointing to the stomach, which also seemed to be contra-indicated by the age and sex of the patient. In Case 3 the converse appeared to be probable, and, accordingly, I turned my attention to the stomach first of all. Case 2 is the one upon which I look back with much regret. The question of the appendix being at fault was considered very carefully, and we both of us came to the conclusion that it was not; but even here, had we been able to get leave to operate earlier, as we wanted to do, the result would probably have been very different. It was a case where an exploratory operation seemed to be absolutely necessary, but, as so often happens, the friends of the patient were dead against it and influenced him to refuse consent until it was too late. I thought this group of cases, which followed close on one another, worthy of being recorded.

# Medical Societies.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

*Adjourned Discussion on Modern Methods of Vaccination and their Scientific Basis.*

A MEETING of this society was held on Jan. 14th, Dr. F. W. PAVY, the President, being in the chair.

Dr. S. MONCKTON COPEMAN, in the first place, repeated that portion of his demonstration which was given at the last meeting of the society and which was fully reported in THE LANCET of Dec. 14th, 1901 (p. 1670), dealing with the transference of variola through monkeys and calves, and the subsequent successful vaccination of the child with the lymph thereby obtained.

Professor SIMS WOODHEAD said that he had performed many experiments in order to test the effect of adding glycerine to calf lymph and he could fully confirm the observations of Dr. Copeman. He said that the addition of 50 per cent. glycerine to lymph had a greater effect in eliminating the non-spore-bearing organisms than the spore-bearing organisms, but that the staphylococcus pyogenes aureus was more resistant to the action of glycerine than other organisms, but that even on this organism it had a considerable effect, since it diminished all but a few—probably about 5 in 1000 being left. The spore-bearing organisms were almost entirely unaffected by glycerine and this seemed to give some indication of the nature of the organism of vaccine, which might be so small as to be invisible to the present power of the microscope. It had been pointed out by THE LANCET Special Commission on Glycerinated Calf Vaccine Lymphs[1] that when the spore-bearing organisms were in excess in the lymph, the collection of the vaccine lymph had not been carried out with all the care that could be desired, and he considered that if a lymph showed many spore-bearing organisms it was a proof that the vaccine had not been properly collected. He then dealt with the effects of glycerine on the activity of the lymph and said that he did not believe that for three or four weeks it diminished the potency, but that after that time the lymph lost some of its activity. He believed that glycerination had most effect on those organisms which grew at the body temperature. It had been stated that "worse" arms and more local inflammation were caused by glycerinated lymph. This he did not believe to be the case, but he asked that the Local Government Board should, if possible, prepare statistics from their returns in order to decide this point.

Dr. T D. ACLAND said that he hoped that the time would oil and iodide of iron for internal use. During the first fortnight after admission the following conditions were noted. The temperature for the first week usually reached 99°F. in the evening, but afterwards became subnormal, with a daily range of less than one degree. No pain was complained of, the bowels acted regularly, and the fluid present in the abdominal cavity seemed to vary considerably from time to time. At intervals of a few days attacks of vomiting occurred, one or more in the day, not preceded by nausea, and unaccompanied by any loss of appetite. The abdomen continued much distended, and at times on manipulation coils of intestine stood out prominently. These coils would remain rigid and hard for a few seconds, then gurgling was heard, followed by visible peristalsis and gradual subsidence of the prominent coils. From the appearance of these coils, the so-called "ladder-like" formation, it was concluded that they formed part of the small intestine and that there must be obstruction at or above the ileo-cæcal valve. The conditions above described increased in intensity during the following five weeks. The vomiting became more frequent, the bowels failed to act save after enemata, the evidence of obstruction became more marked, and the child was rapidly losing ground.

---

[1] THE LANCET, April 28th, 1900, p. 1227.

On Nov. 5th, seven weeks after admission, the abdomen was opened by a median incision about four inches long, extending an inch above the umbilicus. A small quantity of straw-coloured fluid escaped. An extensive condition of tuberculous peritonitis was found, the small intestines being congested, distended, and everywhere studded with numerous tubercles, ranging in size from pins' heads to peas, the larger being white and evidently caseous. There was not a great deal of matting of the intestines, but some bands were found and divided. The omentum did not come into view, but the mesenteric glands were enlarged and caseous. On examining the state of the intestines towards the lower end of the ileum a hard nodular portion was found which was evidently the seat of the obstruction. The bowel at this point was much thickened all round, evidently in connexion with an extensive tuberculous ulceration of the interior, and the lumen was practically obliterated. An anastomosis was made between the portions of the intestine above and below this mass, but it was impossible to find any healthy intestine and tubercles were present in the opposed portions of the intestine. The anastomosis was performed in the ordinary manner by a double row of sutures and the abdomen was closed in the usual manner.

The patient was in a collapsed condition for some time after the operation, which lasted about an hour, but rallied well next day. The wound healed well with the exception of a small part at the lower end where a stitch had given way, but this also was well in a fortnight. There was not much alteration in the abdominal condition for some time after the operation. One month later it was noted that the abdomen continued distended and tense and that occasionally visible peristaltic movements were produced on manipulation. The acute obstructive symptoms subsided after the operation and the child took her food well. Two months after the operation the abdominal condition had greatly improved. The abdomen was now soft although still rather distended, an ill-defined thickening could be made out on the right side, as seen at the operation, but no visible peristalsis could be elicited. There was still apparently some free fluid present. The child had gained four pounds in weight. Four months after the operation she was in good health, running about all day and eating well. On examination of the abdomen nothing abnormal could be detected in the form of thickening, distension, or fluid. At the end of 18 months she was in excellent health and had passed successfully through attacks of pneumonia, measles, and diphtheria.

*Remarks.*—The symptoms in this case were clearly due to tuberculous peritonitis with obstruction of the bowel. Operative treatment was adopted, first as in itself a valuable therapeutic agent, and secondly for the relief, if possible, of the intestinal obstruction which was threatening the patient's life. The recovery of the patient was remarkable and unexpected. The child was in such a serious condition that it was very doubtful if she could rally from the shock of the operation, while the portions of intestine applied to each other were so diseased that failure of union and subsequent fæcal extravasation seemed very probable. At the time the question arose as to resection of the tuberculous mass and end-to-end suture, but this was considered inadvisable from the weak condition of the child and the diseased state of the intestine. The result of the operation is a striking example of the mysterious influence of laparotomy on the course of this affection, even although none of the disease is removed. No doubt in early cases of tuberculous peritonitis it is well if possible to remove the primary focus, but the great majority of cases in which surgical interference would be considered are so advanced and extensive that any attempt of this kind would be very likely to end fatally. Cases like the above show that such radical measures are not always necessary.

---

## SOUTH DEVON AND EAST CORNWALL HOSPITAL.

### THREE CASES OF GRAVE ABDOMINAL INJURY SHOWING THE DIFFICULTY OF FORMING A CORRECT DIAGNOSIS.

(Under the care of Mr. C. E. RUSSEL RENDLE, assistant surgeon to the hospital.)

IN the following three cases the difficulty which is often experienced of diagnosing acute abdominal disease is well exemplified. In the first case a ruptured gastric ulcer was mistaken for an appendicitis. The sex and age of the patient were certainly in favour of the diagnosis of rupture of an appendix, but the very sudden onset might incline the diagnosis towards a rupture of a gastric or duodenal ulcer. A history of dyspepsia is encountered in more than nine-tenths of the cases, and the absence of such a history was certainly against the gastric lesion. This was typically a case for early exploratory laparotomy. In the second case an appendicitis was thought to be an acute intestinal obstruction, but it does not appear from the notes that at any time vomiting was marked or even that it occurred at all. On the whole, the evidence was in favour of peritonitis from extravasation. In the third case the diagnosis of a ruptured gastric ulcer, though at the operation found to be erroneous, was fully justified when the long history of dyspepsia is considered, though the onset was not very rapid. In all such cases the danger of an early exploratory laparotomy is slight—very much less, indeed, than the risk the patient will run if the case be left. As to the part of the abdomen to be first opened, this must depend on the provisional diagnosis, and even should it be wrong, the increase of the risk to the patient is but slight.

CASE 1.—A man, aged 56 years, was admitted into the South Devon and East Cornwall Hospital about noon. On the previous afternoon about four o'clock while carrying a heavy beam in H.M. Dockyard, Devonport, he felt a sudden agonising pain in the abdomen. He was taken to the surgery and was sent home in a cab. A medical man relieved the pain by morphia, but the patient refused to go at once to the hospital. When admitted he was under the influence of morphia, and as no one went with him it was impossible to be certain of his statements, but he persisted that he had been perfectly well up to the time of his accident. He had a normal temperature and a good pulse of 84. He did not complain much of pain and suffered fairly deep palpation, the abdomen being only a little distended; liver dulness was present and some respiratory motion also. As the theatre was in use at the time and as his condition appeared to be so good, Mr. C. E. Russel Rendle decided, in consultation with one of his senior colleagues, to defer operation till four o'clock, making a provisional diagnosis of ruptured appendix. When Mr. Rendle returned to the hospital at 3 45 P.M. he saw the patient's wife, who confirmed his statement as to his general good health, saying that he had not been ill for years, save that on the evening prior to his attack he had a stomach-ache and went to bed early, having a hot poultice. On the next morning, however, he appeared to be quite well, went to work, and ate his dinner as usual. On being questioned as to dyspeptic symptoms she said that he did not know the meaning of indigestion. When Mr. Rendle saw the patient, however, his condition had very seriously changed for the worse and it was with grave misgivings that he prepared to operate. The abdomen was opened through the right rectus and the peritoneal cavity was found to be full of semi-purulent turbid fluid. The appendix was found to be healthy, no ruptured bowel could be seen, and it was concluded that a ruptured gastric ulcer must be the cause of the symptoms.

any doubtful case, and especially those cases in which the patients were still comparatively young He did not think that all cases of chronic enlargement of the head of the pancreas did well, and he referred to one case of a man who at the time of operation was thought to be the subject of malignant disease, but at the necropsy the head of the pancreas was found to be the seat of chronic inflammation. He did not think that it was possible in many cases to push a gall-stone back along the common duct into the gall-bladder.

Mr. A. E. Barker said that from time to time cases were met with which were believed to be cancer and in which the patients made good recoveries. He referred to the case of a woman in whom he had explored the abdomen and had found what he considered to be cancer and accordingly had given a grave prognosis. The patient made a good recovery and was well a year after the operation. He thought that celerity in operating and protection to the patient from cold did most to eliminate shock.

Mr. W. G. Spencer suggested that the duration of the disease was an important factor in the diagnosis, for in those cases which ran a rapid course the disease was commonly situated in the head of the pancreas, whereas in those of more chronic course the growth might be secondary to the irritation caused by gall-stones. He suggested that some cases might be due to the occurrence of gumma of the liver and deprecated operation in such cases.

Mr. J. Hutchinson, jun., did not consider that rapidity of operation was so important as Mr. Mayo Robson considered, for in operations on the lower abdomen the most successful results were obtained by the slower operators. In comparing cases of intestinal obstruction in which a Murphy's button had been used with those which had been sutured, the mortality was less in those sutured (although a longer operation) than it was in those in which a Murphy's button was used. He asked if in the treatment of cases of ascites stitching the omentum to the abdominal wall had been shown to be of any service. With regard to those cases in which cancer was seen at the time of the operation and yet the patient recovered he said that he did not believe that it was the effect of the operation, and he mentioned the case of a man with ascites, jaundice, and lumps in the liver who recovered without any operation.

Dr. A. F. Voelcker asked what dose of calcium chloride had been used in these cases.

Mr. Mayo Robson, in reply, said that he gave 30 grains of calcium chloride three times a day for from two to three days before operating and one-drachm doses with saline solution per rectum subsequently to the operation. He mentioned a case in which chloride of calcium had proved of good service in arresting hæmorrhage. He was convinced that it was inadvisable to operate in cases of cancer of the head of the pancreas.

---

# CLINICAL SOCIETY OF LONDON.

*The Radical Treatment of Chronic Tuberculosis of the Intestine.—A Case of Hair Ball removed from the Stomach of a Child, aged Nine Years.*

A meeting of this society was held on Jan. 10th, Mr. Howard Marsh, the President, being in the chair.

Mr. A. W. Mayo Robson (Leeds) read a paper on the Radical Treatment of Chronic Intestinal Tuberculosis, in which he observed that whatever might be their views regarding the treatment of acute intestinal ulceration surgical treatment was generally advisable in chronic intestinal tuberculosis. He related seven cases (one male and six females) in which he had operated with only one death, and remarked that while in the first and seventh of his cases the adhesions to adjoining parts were very intimate in the other cases the affected part of the bowel was quite free, thus rendering operative measures easy and simple. In the first, second, third, and fifth of his cases he had employed a decalcified bone bobbin as a temporary splint over which to apply sutures, a method which he had described on numerous occasions and which he still employed and advocated as being simple and efficient. The physiological rest to the diseased parts secured by short-circuiting, as in his third case, and by colotomy, as in his sixth case, seemed to answer so well that where the radical operation of excision involved serious difficulties or the patient was not in a condition to bear it he would not hesitate in future to be content with similar procedures and then to trust to general treatment and hygienic surroundings to assist in the cure. If in the future operative treatment should be thought advisable in acute cases he anticipated that short-circuiting the diseased area would be found to be the more useful procedure, as it was the easier and safer method to pursue, but experience alone would show whether the suggestions would prove of as much service in acute as they were in chronic cases. It was interesting to note that in his first and seventh cases, in which a condition of tuberculous peritonitis coexisted with tuberculous ulceration of the intestine, the mere exploratory operation had not cured or even arrested the tuberculous process, but that the radical operation of removing the principal focus of disease or, as in his third case, the short-circuiting and so setting at rest the diseased bowel, was in all three cases effectual in putting a stop to the tuberculous peritonitis and, so far as could be seen without the parts being exposed, in curing the more diffuse disease. All surgeons must have had the experience of curing tuberculous peritonitis by simple abdominal section, with or without drainage, and probably many of them had also experienced disappointment in other cases where the effusion had returned after a longer or shorter interval. He suggested that the explanation of these recurrent cases lay in the fact that the original focus of disease in the ovaries, Fallopian tubes, or bowel, had not been removed and had again been the starting-point for a further effusion of the tubercle throughout the peritoneal cavity. If that were the correct explanation the remedy was quite clear—viz, that wherever the original disease might be it should be removed, if that were possible without adding seriously to the risk of operation.—Dr. W. Ewart asked what were the early symptoms which led to the diagnosis of tuberculous ulceration of the intestine and what were the indications for operation He also asked if tuberculin had been used as a means of diagnosis.—Mr. Charters J. Symonds pointed out that the symptom which in the cases recorded had led to operation was obstruction and that operation had been performed rather for the relief of obstruction than for the treatment of ulceration of the intestine. He quoted the case of a female, aged 25 years, who had recurring attacks of mild appendicitis. The appendix had been removed and a fæcal fistula had formed when she first came under observation. The cæcum was excised and an end-to-end union of the intestine was made. At the time of the operation tuberculous ulceration of the intestine was seen to be present He mentioned two other cases of possibly tuberculous stricture of the small intestine in men. One of these patients had been subject to symptoms of obstruction for 20 years. In this case two feet of enormously distended intestine were excised. In the other case a man, aged 40 years, was too ill to stand the excision of the intestine but the gut was short-circuited. He thought that Mr. Mayo Robson's suggestion of removing the localised focus of tubercles was a good one.—Mr. W. Watson Cheyne said that there were two important points for discussion: the first was the treatment of tuberculous ulceration by excision or short-circuiting, and the second was whether the focus of the tuberculous disease should be searched for and removed. He quoted the case of an infant with extensive tuberculous disease of the peritoneum with symptoms of obstruction. In this case he short-circuited the intestine and at the time of the operation tubercles were seen all over the peritoneum. The child made an excellent recovery. He was convinced that the treatment of tuberculous ulceration of the intestine by *short-circuiting* was sound practice, but he considered it debateable whether the searching for and removal of the original *focus* were *advisable*, though, of course, where the disease was strictly limited—as, for instance, to the Fallopian *tubes—these should be* removed. In diffuse tuberculous peritonitis it was inadvisable to search for the focus as the patient could seldom stand the prolonged operation.—Dr. G. Newton Pitt thought that the operation in the cases recorded was performed rather for obstruction than for ulceration of the intestine. He considered it inadvisable to interfere with cases in which there was "matting" of the intestines. Although tuberculous affections of the appendix were not uncommon at post-mortem examinations he thought that tuberculous appendicitis was decidedly rare.—Mr. A. E. Barker said that he had removed a tuberculous mass from the abdomen of a little girl in the region of the not be far distant when the Government would take steps to supply a standard lymph throughout the country. He divided the subject into three main headings: (1) the origin of vaccine lymph; (2) the preparation of vaccine lymph, especially in relation to its purification, standardisation, and storage; and (3) the use of the prepared lymph, especially in relation to methods of vaccination, dosage, efficiency of vaccination, and the question as to the extent and duration of after-effects or complications of vaccination. He pointed out that although vaccination was in vogue more than 100 years ago it had been outstripped in the scientific details of technique by many of its successors in the department of protective inoculation. He said that glycerine had long been used to dilute lymph, but that until the research of Dr. Copeman it had not been used as a scientific means of freeing the lymph from extraneous organisms. He then referred to the standardisation of lymph by inoculating rabbits and said that in this way the potency of any particular lymph might readily be tested before being sent out without having resort to the necessity of vaccinating infants. He said that this method had been carried out at Lille with great success for over two years. He considered that vaccination as practised was open to two main objections, firstly, the necessity for creating a local sore which proved a possible starting point for various inflammatory complications; and secondly, that in the homes of the poor the vaccinated child imposed an extra burden on the already overworked mother. He next dealt with the extent and number of vesicles produced and thought that there ought to be a fixed irreducible minimum below which no certificate of successful vaccination should be given. Lastly, he referred to the treatment of variola by the antitoxin of vaccinia and stated that cases had been thus treated with serum taken from a calf which had been vaccinated four weeks previously. The observations were, however, inconclusive. He gave notice of the following motion:—

> That in the opinion of this meeting of Fellows of the Royal Medical and Chirurgical Society it is desirable that the Government should without delay make such additions to the national vaccine establishment as shall enable it to supply glycerinated calf-lymph to all medical practitioners who may desire to use it; and that, in view of the national importance of the subject, steps should be taken to test and regulate the sale of all imported lymph and to inspect the manufacture of all that is made in this country.

Professor HACCIUS (Geneva) said that in 1892 he experienced considerable difficulty in obtaining good lymph in calves and cow-pox could not be found. He therefore attempted to transmit variola to the calf; in this he was successful, and after passing the virus through seven calves he then inoculated a child with the result that typical vaccine vesicles were formed. These results he published, but Professor Chauveau of Paris held that the disease in the calves was vaccinia and not modified variola, and further Professor Chauveau inoculated a cow with variola and from the vesicle produced inoculated a child who developed typical variola. He (Professor Haccius), however, explained the last result as being in reality due to the direct transference of the variola virus, the cow being merely a stage in its transference. He said that Dr. Stumph of Munich had carried out experiments similar to those of his and had confirmed his results. It was well known that all cases of variola could not be thus transmitted to the calf, but he believed that the identity of vaccinia and variola would be proved.

*The discussion was adjourned.*

A demonstration with the "Epidiascope" was given after the meeting.

## MEDICAL SOCIETY OF LONDON.

### *Observations on the Surgical Treatment of Obstructive Jaundice, resulting from an Experience of over 200 Operations.*

A MEETING of this society was held on Jan. 13th, Dr. W. H. ALLCHIN, the President, being in the chair.

Mr. A. W. MAYO ROBSON (Leeds) read a paper upon the above subject. He said that his recent operative experience in cases of chronic obstructive jaundice, especially in those associated with gall-stones and with chronic pancreatitis, had led him to take a more hopeful attitude in considering the treatment of deeply jaundiced patients from a surgical standpoint. The first and often the most difficult question was that of diagnosis, and the following causes of jaundice must be taken into consideration: (1) common duct cholelithiasis; (2) chronic pancreatitis; (3) simple stricture of the common bile-duct; (4) inflammatory adhesions causing pressure on, or stenosis of, the hepatic duct or of the common bile duct; (5) hydatid disease of the liver pressing on or discharging into the bile ducts; (6) gummata implicating the ducts; (7) chronic catarrh of the bile ducts; (8) cancer of the common bile-duct; (9) cancer of the head of the pancreas; (10) cancer of the liver associated with jaundice either due to catarrh or pressure; (11) cirrhosis of the liver; and (12) other rare causes, such as aneurysm of the hepatic artery or of the aorta and other tumours of the liver, the gall-bladder, the pylorus, the kidney, or the intestine pressing on or occluding the common bile duct. Surgery held out good prospect of cure in the first five causes enumerated. Medical treatment alone was advisable for the sixth and seventh causes and in the remainder with certain exceptions relief could only be hoped for. Mr. Mayo Robson then dealt with one or two points which he had found of use in guiding him to a conclusion as to whether the case was suitable for an exploratory operation or not. He said that a painless onset of chronic jaundice must always give rise to the suspicion either of chronic catarrh dependent on cancer of the liver, or of occlusion of the hepatic or common bile duct by growth, and if this were associated with distension of the gall-bladder and rapid loss of weight and strength, cancer of the head of the pancreas would probably be found. On the other hand, the history of an attack of pain followed within from 24 to 36 hours by jaundice was strongly suggestive of cholelithiasis. Enlargement of the liver was much more common in obstruction due to cancer than it was in that from gall-stones. The presence of ascites was suggestive of malignant disease. The jaundice of gall-stones was rarely continuous but it increased and diminished from time to time, whereas the jaundice of obstruction due to growth steadily increased. Fat in the motions and glycosuria with very rapid wasting were suggestive symptoms of pancreatic trouble. A rigid right rectus abdominis and tenderness, one inch above and to the right of the umbilicus were suggestive of gall-stone trouble, as was McBurney's tender spot of appendicitis. The question as to treatment depended on the diagnosis. 1. If the diagnosis was doubtful an exploratory operation was advisable, providing that the general condition of the patient rendered it probable that such a procedure *per se* would not hasten death. 2. If malignant disease was positively diagnosed operation could, with some few exceptions where it had been possible to completely remove it, do but little good. 3. If gall-stones, or in fact any of the first five enumerated causes, were diagnosed, operation was decidedly advisable. Mr. Mayo Robson then proceeded to consider these three conditions, and he quoted five cases regarded as hopeless which had been operated on with good success; these cases, he said, supported his first proposition. With regard to the second proposition he considered that there were two classes of cases in which operation could do no good—(*a*) primary cancer of the liver and (*b*) cancer of the head of the pancreas—but in young patients the question of operation should always be considered, as malignant disease of the pancreas was not common until middle age. Three cases were quoted which showed that in forms of cancer other than those mentioned relief or apparent cure had resulted from operation. With regard to the third proposition operation was urgently demanded. 212 patients suffering from obstructive jaundice dependent upon one or other of the causes above mentioned had been operated on. Of these 183 recovered, showing a mortality of 13·6 per cent. A careful study of the causes of mortality showed that the two greatest dangers were hæmorrhage and shock and the two next serious causes were exhaustion and sepsis. The employment of chloride of calcium in large doses had been an efficient means in controlling the hæmorrhage, and the administration of strychnine and large saline enemata, with or without brandy, half an hour before operation had diminished shock. But of even greater importance was the cultivation of the habit of operating expeditiously, and even the most complicated cases should not occupy more than an hour.

Mr. J. H. MORGAN said that the success of the operation evidently depended on the accuracy of the diagnosis which had preceded operation and that that accuracy had been derived from experience. He considered that rapidity of operation was most important and that shock could be largely avoided thereby.

Mr. F. S. EVE said that he thought it advisable to explore ference; (2) a Calculus removed from the pelvis of a kidney; (3) a large Gall-stone; (4) a Tubal Gestation; and (5) Some Fibroid Tumours.

Dr. D. BERRY HART showed a Microscopical Section of Actinomycosis of the Ovary.

Dr. A. C. SANDSTEIN sent a paper on the Movements of the Pelvic Bones during the Operation of Symphysiotomy and the true function of the Section of the Pubic Symphysis. The paper was communicated by the Secretary. The conclusions arrived at were based on a study of symphysiotomy on 28 recent female cadavera taken at random in the post-mortem theatre. All the pelves except two had true conjugates of over four inches. The movements that occurred during and increased with the separation of the pubes after symphysiotomy were as follows. The first was the movement of the pubes outwards by rotation of the innominate bones on vertical axes passing through their respective sacro-iliac joints. The outward rotation could only increase the sacro-pubic diameter to a very limited amount. For although each pubis was carried further from the sacral promontory than it was before, yet it was not so with the line joining the two pubes, which, indeed, in some shapes of pelves might even be carried nearer the sacral promontory. The second movement consisted in rotation of the innominate bones on a horizontal transverse axis passing through the sacrum, and carried the pubes downwards. This was estimated by measuring the exact vertical height of the centre of the sacral promontory above the upper end of the symphysis pubis before symphysiotomy, and after it above the line joining the upper ends of the separated pubes. Careful measurements were made with degrees of separation varying from one to eight centimetres; it was found that there was positive proof of the existence of that movement of the innominate bones, and one might at least calculate on a depression of the pubes of 1·4 millimetres for each centimetre of pubic separation. The third movement consisted in rotation of the innominate bone on its own long axis (an axis lying as it were in a direction from the posterior superior spine to the ilio-pectineal eminence), so as to cause the ilium to become more erect (or vertical). In every case with each increment of pubic separation there was increase of the distance between the anterior iliac interspinous diameter and the horizontal level of the symphysis pubis. Roughly speaking, six centimetres of pubic separation gave an increase of one centimetre. An examination of all the results showed that the diameters lying more or less transversely were increased greatly by each centimetre of pubic separation and a very small amount of pubic separation would enlarge these sufficiently to let the fœtal head pass. But unfortunately it was more usually the true conjugate that presented the difficulty, and six centimetres of pubic separation enlarged that only about one centimetre or two-fifths of an inch on an average. Here separation of the pubes increased greatly the transverse diameters and sometimes increased the true conjugate, but it might even diminish the true conjugate. The downward movement of the pubes increased the true conjugate and the rotation of the innominate bones increased the downward movement of the pubes. Walcher's position should therefore be used, though greater effects were obtained with symphysiotomy. With regard to the safety of symphysiotomy Dr. Sandstein especially watched the result of the separation of the pubes on the sacro-iliac joint; in 44 per cent. rupture of the ligaments began below six centimetres of separation, while in 56 per cent. it began at or above that point. In three pregnant women it began only at eight centimetres in two, and not even at that in one. The vulva was greatly affected by the separation of the pubes, the parts between the bones becoming stretched like a drum; up to five or six centimetres the strain was well borne, in only one did a tear occur at six centimetres. After seven centimetres it was evident that there would be a great risk of necrosis and sloughing of the stretched tissues. The bladder and urethra would only be involved secondarily by a tear or through sloughing. Dr. Sandstein collected the results of 300 recorded cases between 1892 and 1898 and found that the danger lay in and around the symphysis pubis. The sacro-iliac joints did not suffer from suppuration or "non-union," though some pain in them was recorded. Lacerations about the vestibule and vulva occurred in 30 cases, hæmorrhage in 38 cases, fistula occurred seven times, local sepsis in 24 cases, and phlebitis in eight cases. 35 deaths occurred and were due to septicæmia or pyæmia in 24 cases and to hæmorrhage in three cases. As a result of his investigations Dr. Sandstein stated that pubic separation should be limited to six centimetres, and as each centimetre increased the true conjugate by 1·67 millimetres, the utmost amount of increase of the true conjugate which could be aimed at was one centimetre, or two-fifths of an inch. Therefore, the cases must be strictly limited to those in which, by an addition of two-fifths of an inch to the true conjugate, they could with safety to the mother deliver a living child by nature alone or aided by forceps or version. The range of forceps was in a true conjugate of from four to three and a quarter inches; symphysiotomy with a maximum of six centimetres separation increased the true conjugate two-fifths of an inch, which when subtracted from three and a quarter inches gave two and seven-eighths inches, or 7·3 centimetres, as the minimum conjugate on which this operation should be performed. Walcher's position should always be used. Sometimes the sides of the pelves moved unequally, with consequent risk of tearing. This could be met by flexing the thigh on the abdomen on the non-moving side, using the bent-up knee of that leg as a lever and abducting it forcibly outwards and downwards; this in his experiments could always make the side share in the movements. The knife should be a broad-bladed one. The symphysis must be completely divided, but division of the sub-pubic ligament should not be aimed at as it prevented extension by tearing of the wound down into the vulva. Rigid asepsis was necessary, and since many fatalities occurred from sepsis in patients with a previous foul vaginal discharge the existence of such a discharge should be considered as a contra-indication to the operation.—Professor A. R. SIMPSON, Dr. HART, Dr. J. W. BALLANTYNE, and the PRESIDENT discussed the paper.

Dr. HART read a paper on a case of Full-term Intact Extra-peritoneal Gestation successfully removed after Five Years' Retention. There was a very clear history of extra-uterine gestation five years before. The physical signs were those of an extra-peritoneal cyst reaching up to the navel. Its presence had given rise to symptoms only produced by the size of the cyst. On operation the cyst contained a thick, grumous fluid, and the bones were either loose or easily detached. There was some flesh and skin on one of the legs and on the scalp. The bones were in a good state of preservation. No trace of the placenta or cord could be found. The sac opening was stitched to the abdominal wound and the sac itself was stuffed with iodoform gauze. The posterior peritoneum had been lifted up as Taylor had described.—Dr. F. W. N. HAULTAIN, Dr. BALLANTYNE, and Professor SIMPSON commented on the case.

Dr. HAULTAIN read a paper on Expulsion of a Dermoid Ovarian Cyst per Vaginam during Labour. The patient was in labour with her third child, and before being seen by Dr. Haultain the pains had continued for 24 hours. A large soft swelling had been detected behind the posterior vaginal wall and an attempt to deliver the child by forceps had been made but ineffectually, the traction resulting in the protrusion of a soft bulging mass from the vulva. On examination afterwards the mass seemed to be free in the canal, and an endeavour to pull it down for inspection resulted in its detachment and removal. No special hæmorrhage occurred and a living child was speedily extracted with the aid of forceps. After expulsion of the placenta a rent was found in the posterior vaginal wall and was treated by packing with iodoform gauze for four days. The patient made a good recovery. Four similar cases were recorded by Luschka, Lomer, Berry, and Trent; in all these cases forceps had been used and all the children were born dead; one mother died. Six cases were recorded of the expulsion of ovarian tumours per anum, and in four of these the result was fatal to the mother. This complication of labour was rare and might be said to occur only once in 4000 cases. If labour were left to the spontaneous efforts of nature a maternal mortality of 50 per cent. was shown; this result indicated the necessity of prompt and energetic treatment. Four methods of management were recognised: reposition of the tumour into the abdomen; assisted delivery of the child, either without diminishing the size of the tumour or after doing so; Cæsarean section and ovariotomy; and vaginal ovariotomy.—Dr. R. G. MCKERRON (Aberdeen), Professor SIMPSON, and Dr. BALLANTYNE discussed the paper and Dr. HAULTAIN replied.

---

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Jan. 10th, Mr. A. Wynter Blyth, the President, being in the chair.—Dr. D. S.

appendix and the child had made a good recovery. He considered that it was inadvisable to interfere with those cases in which there was "matting" of the intestines and in such of these cases on which he had operated he had always regretted it, as the wound had opened up and fæcal fistulæ had formed, the final condition of the patient thereby being rendered very distressing. The cases most suitable for operation were those with a considerable amount of fluid. He did not think that tuberculous disease of the appendix was of common occurrence. He then entered on the question of how much of the intestine might be safely removed and mentioned a case in which the cæcum, the ascending, the transverse, and the descending colon had all been successively removed for tuberculous ulceration and the patient after the final operation remained in excellent health.—Mr. C. R. B. KEETLEY thought that it was important in all cases of tuberculous peritonitis to find the point from which the disease had arisen. He classified the cases under three headings—the first, cases in which a tumour could be felt (this, he said, was always glandular); the second, cases in which there was a tuberculous appendicitis; and the third, cases in which there was diffuse tuberculous peritonitis. He quoted a case in which he had removed some suppurating glands in the mesentery and the patient had made a good recovery and he considered that the presence of enlarged glands in the mesentery was a valuable indication of the seat of the disease and should always be looked for at the time of the operation. He considered that patients with abdominal tuberculosis usually stood the severe abdominal operation very well.—Dr. NORMAN DALTON mentioned the case of a girl, aged 12 years, who was taken acutely ill with symptoms of appendicitis. The abdomen was opened and the peritoneum was seen to be thickly studded with tubercles. The girl made a good recovery.—Dr. PERCY KIDD referred to the difficulties of diagnosing ulceration in early cases of the disease. He thought that in most cases there was also disease of the lungs. Multiple ulcers of the intestine were generally found and these were more common in the cæcum than in the ileum, and it was curious that tuberculous appendicitis was not more common considering how frequently this region was the seat of tuberculous ulceration.—Mr. MAYO ROBSON, in reply, said that out of some 300 cases of appendicitis in which he had operated five had been tuberculous. He considered that loss of flesh, diarrhœa, abdominal pains, and night sweats were the symptoms upon which he had relied for the diagnosis of ulceration of the intestine. He believed that the removal of the focus of the disease was most important.

Dr. E. PERCY PATON read a paper on a case of Hair Ball in the Stomach of a Child, aged Nine Years, which was successfully removed. The patient was an intelligent girl in whom a lump was accidentally found in the epigastric region. As she was known to have eaten hair and other similar substances since she was three years old and had only been broken of the habit recently a hair ball was diagnosed. There were no gastric symptoms. On opening the stomach a mass, consisting chiefly of the child's own hair, seven inches long, weighing seven and a quarter ounces, and having the general shape of the stomach, was extracted. The child recovered without a bad symptom,

## OBSTETRICAL SOCIETY OF LONDON.

*Chorio-epithelioma with Pulmonary Metastases.—Pneumococcic Meningitis.—Exhibition of Specimens.*

A MEETING of this society was held on Jan. 1st, Dr. PETER HORROCKS, the President, being in the chair.

Dr. CUTHBERT LOCKYER read a paper on a case of Chorio-epithelioma with Pulmonary Metastases, in which the evidence of an abortion lay in the fact that the patient lost blood freely four months before admission, the loss continuing until she was sent to hospital. The patient was 42 years of age. She had given birth to seven children. The last confinement took place three and a half years before admission into the Samaritan Hospital. Three abortions were recorded, the last being 13 years before the patient was sent to the above hospital. She was admitted with evident uterine enlargement and in a condition which prohibited operative interference. The uterus was perforated by a new growth in its walls and secondary deposits were found in the lungs. The pathological characters of the primary and secondary growths were described, pathological proof of the occurrence of chorio-epithelioma following immediately on the removal of hydatidiform mole was given, and the paper was followed by a lantern demonstration on the close association between vesicular mole and chorio-epithelioma.—The PRESIDENT remarked that it was quite impossible to prove definitely whether these malignant growths were of maternal or of fœtal origin. Even if it could be shown that they were developed from the outer epithelial layer of the villi of the chorion, that would not settle the question, because it was still disputed whether that layer was maternal or fœtal. It was for this reason that he had named his own specimen, shown at the society some months ago, "deciduoma malignum," the name given by Sänger who first described the condition. He could not help leaning to the view that it was fœtal in origin, and he did not see how those who believed in its maternal origin could get over the fact that it so often followed upon hydatidiform mole. The point raised by Dr. Lockyer that there were two sorts, one without syncytial elements, probably maternal in origin, to which the term "deciduoma malignum" would be appropriate, and one with syncytial elements of fœtal origin, to which the term "chorio-epithelioma" would be better applied, was no doubt very important. But it had to be proved. Could, for instance, Dr. Lockyer say that in all cases of this malignant growth which had followed vesicular mole there had been syncytial elements? In every instance of this malignant growth it was very desirable to investigate thoroughly the question of a recent pregnancy, miscarriage, or parturition. In his own case this had been very difficult to ascertain. The woman was 48 years of age and had had a child two or three years previously. The growth was typical and contained syncytial elements.—Mr. ALBAN DORAN stated that when the patient was admitted into his wards she was too ill for any operation. At first sight sloughing fibroid seemed probable, but on further examination extensive malignant disease was evident. It was remarkable that she lived so long. Dr. Lockyer was to be congratulated upon his excellent report of the pathology of this case. Many similar cases must have been overlooked or misinterpreted.—Dr. HERBERT SPENCER said that while he agreed with Dr. Lockyer's views in the main, he thought it would for the present be better to use the term "deciduoma malignum" until a little more was known about the pathogenesis of the disease. There was no doubt that two distinct classes of growth had been described under this name. But Klebs, who was, he thought, the first pathologist to investigate the disease, had hesitated whether to describe it as a cancer or a sarcoma, and the late Dr. Kanthack had stated his decided opinion that his (Dr. Spencer's) case, which showed large masses of typical syncytium, was a sarcoma. He thought therefore that it was a little premature to style it a "chorio-epithelioma," though personally he was inclined to regard the syncytial growth as of that nature.—Dr. LOCKYER, in reply, stated that the patient's history afforded no proof of a period of amenorrhœa prior to the onset of hæmorrhage which began suddenly in June and continued until November, 1900. He thought that the syncytial masses were of chorionic origin and if a chorionic villus was entirely fœtal it followed that any neoplasm arising therefrom must likewise be of fœtal origin. He adopted this nomenclature of "chorio-epithelioma" for his specimen, believing that the syncytial envelope of a chorionic villus was an epiblastic fœtal structure. The term "syncytial carcinoma" would be equally applicable in the case of these new growths.

Dr. THOMAS WILSON (Birmingham) read a short communication on a fatal case of Primary Pneumococcic Meningitis simulating Puerperal Eclampsia, in which there was 1·5 per cent. of sugar in the urine but only a cloud of albumin.

Dr. A. H. N. LEWERS showed two specimens of Cancer of the Body of the Uterus removed by abdominal panhysterectomy.

## EDINBURGH OBSTETRICAL SOCIETY.

*Exhibition of Specimens.—The Movements of the Pelvic during Symphysiotomy.—Full-term Intact E Gestation.—Expulsion of a Dermoid Ovarian Vaginam during Labour.*

A MEETING of this society was held on Jan. RITCHIE, the President, being in the chair.

Dr. N. T. BREWIS showed: (1) A Cyst weighing 48 pounds and measuring 48 in exhibited a young man, aged 18 years, who had been the subject of (unilateral) Acute Cellulitis of the Larynx, believed to be due to a foreign body.—Mr. Lennox Browne exhibited a female patient, aged 14 years, the daughter of a medical practitioner, who had been the subject of Adenoids, and in whom deafness, almost inarticulate speech, mental hebetude, and chorea were prominent symptoms. After removal of the adenoids the patient, with the consent of Dr. Ferrier, had undergone breathing and movement exercises which had led in two months to the doubling of her vital capacity, increase of her chest girth, cure of her chorea, and very marked improvement in her speech and intellect — Dr. W. Culver James showed a female patient, aged 18 years, suffering from Aphonia, with loss of Speech.—Mr. Mayo Collier exhibited a female child, aged nine years, the subject of Defective Speech, associated with Defective Hearing almost to the extent of deaf-mutism, in whom great improvement in both conditions had followed on the removal of a large mass of impacted cerumen which had probably accumulated and been undetected in consequence of a curious abnormality in the meatus.—Mr. Lennox Browne exhibited five patients the subjects of Lingual Varix, one of whom was a medical practitioner; the other four had been sent to him by hospital colleagues as examples in patients at present attending the out-patient department, a point emphasised by the President.—Mr. Mayo Collier referred to an extreme case of Paroxysmal Dyspnœa, the sole reason for which appeared to be lingual varix. Treatment by the galvano-cautery had resulted in a remission which had now lasted for three years.—Dr. Atwood Thorne exhibited a patient with Deafness associated with Nasal Stenosis and Hyperostosis at the Isthmus of the External Auditory Meatus.—Remarks were made on this case by the President, Mr. Mayo Collier, and Dr. Wyatt Wingrave.—Mr. W. J. Chichele Nourse showed a case for opinion which, having many signs of a Malignant Growth of the Left Vocal Cord, had so improved under biniodide of mercury as to suggest its being a gumma.—The President suggested that the case should be watched and further reported on at the next meeting —Mr Lennox Browne read the notes (1) of two cases of Acute Ulcerative Tonsillitis, which had been followed by orchitis, with an acute pustular inflammation of the skin of the penis and the scrotum; and (2) of a case of Posterior Tongue-Tie, with Hypertrophy of the Lingual Tonsil, occurring in a female board school teacher, aged 23 years. A drawing illustrated that the epiglottis stood up, showing all its glossal surface, as well as the lingual tonsil. Removal of the latter and snipping of the central glosso-epiglottic fold resulted in immediate restoration of the parts to the normal.—Dr. P. H. Abercrombie, who had seen the patient both before and after treatment, testified to the striking peculiarity of the appearances as witnessed before and after treatment.—Mr. Lennox Browne also read notes of a case of Pulmonary Tuberculosis in which, bacilli being numerously present, the patient showed continuous gain of body weight during four years of observation.—Dr. Wyatt Wingrave spoke of the histological characters of the bacilli in this case, remarking especially on their tendency to degeneration with development of fresh organisms, and from the presence of pus corpuscles he believed the case to be one of localised pulmonary abscess of a tuberculous nature.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 1st, Dr. E. C. Kingdon, the President, being in the chair.—Dr. G. M. Lowe of Lincoln read a paper on the Use of X Rays in Medicine and Surgery. He used the current from the city main at 230 volts pressure controlled by two of Con's electrolytic breaks coupled in series. With a current of from nine to 11 ampères and at a distance of from 14 to 24 inches of the anode from the plate he got excellent negatives in from five to 30 seconds. The prints exhibited were on Otto paper showing perfect proportion and exquisite detail. Dr. Lowe laid great stress on the importance of a uniform method of work, the anode always being plumb over the part to be radiographed and both sides symmetrically exhibited so that the surgeon could interpret the results correctly. In medicine he had found the rays useful in the diagnosis of hæmatoma, aneurysm, enlargements of the heart, the spleen, and the liver, as well as in renal and vesical calculi. He had frequently observed splenic enlargement amongst the so-called dyspeptic clerks and other employés working in the large foundries on the banks of the Witham, where the subsoil was a wet sand overlying a thick bed of peat. He described a case of Lupus Vulgaris (previously twice scraped) which was now quite healed after about 17 applications of the x rays at a distance of six inches from the part, the rest of the face being protected by a metal mask. After describing and comparing with each other the Finsen ultra violet rays, the Bergused rays, and the x rays, Dr. Lowe showed that all radio-active agencies had at least one property in common—viz., their power of ionising the air—i.e., of rendering the air a conductor of electricity, as shown by the gold leaf electroscope. Lord Kelvin had demonstrated that a bar of iron loaded with positive electricity and insulated by paraffin wax could be discharged or de-electrified by the x rays, and Dr. Lowe put forward the probable theory that this property acting on a limited area of skin and subjacent tissues, when the tube was brought within a few inches from the surface, was the cause of dermatitis and other therapeutic results by acting on the trophic nerves of the parts. X-ray workers were, he stated, daily meeting with remarkable effects which when collected and formulated would revolutionise certain branches of therapeutics.—At the conclusion of Dr. Lowe's address Dr. C. H. Cattle, Dr. J. S. Bolton, Dr. F. H. Jacob, Mr. A. R. Anderson, Dr. F. D. Blandy, Mr. Simpson, and the President spoke on the subject, and Dr. Lowe replied.

GLASGOW SOUTHERN MEDICAL SOCIETY. — A meeting of this society was held on Dec. 26th, 1901, Dr. John Stewart, the President, being in the chair. According to arrangement the meeting was an open one for professional conversation, and the subject suggested for discussion was, What are Scheduled Poisons? In view of recent proceedings of the General Medical Council great interest in the question was manifested, and attention was drawn to the dubiety existing in many minds as to the drugs regarded as poisonous within the meaning of the Pharmacy Acts. After a lengthy discussion it was resolved to appoint a committee to inquire as to what drugs were included under the term "scheduled poisons," and especially those described in the Acts as "poisonous vegetable alkaloids and their salts."—The President, Dr. J. Forrester, Dr. T. Russell, Dr. C. E. Robertson, Dr. D. Young, Dr. J. Fraser Orr, and Dr. A. Wauchope were elected to form the committee, with power to add to their number, and were instructed to report the result of their investigations to a future meeting of the society.—The meeting then proceeded to consider the recent edict of the General Medical Council with reference to the keeping of open shop or medical halls and unqualified drug assistants. After some discussion it was unanimously resolved to protest as a society against the terms of the edict. The council of the society was instructed to draw up a protest for presentation to the General Medical Council at its next meeting.—The ninth meeting of the society of the present session and the first of the new year was held on Jan. 9th, Dr. Stewart, the President, being in the chair. The meeting took the form of a smoking concert, supper, and conversazione. There was a good attendance of members and friends. Supper was served at 9 o'clock, after which an adjournment was made to another room where a pleasant evening was spent in song and story.

BRISTOL MEDICO-CHIRURGICAL SOCIETY. — The fourth meeting of the session of this society was held on Jan 8th, Dr. Barclay J. Baron, being in the chair.—Mr. C. K. Rudge was elected on the Library Committee in the place of Mr. L. M. Griffiths resigned. A cordial vote of thanks was passed to Mr. Griffiths for having acted as librarian for so many years —Dr. F. W. Crossman showed a patient with a loud Aortic Bruit.—Dr. T. Fisher, Dr. P. W. Williams, Dr. E. J. Cave, Dr. E H. E. Stack, Dr. J. Michell Clarke, Dr. A. J. Harrison, and Dr. Newman Neild spoke on the condition —Mr. G. Munro Smith showed the following specimens: (1) Concretion from a Horse's Intestine; (2) Renal Calculi; (3) a Tonsillar Calculus; and (4) Necrosis of the Clavicle (the patient was shown).—Mr. J. Handcocke Wathen showed a series of Concretions from Horses' Intestines —Mr. W. Roger Williams, Dr. Cave, Dr. T. Fisher, Dr. E. Markham Skerritt, Dr. W. K. Wills, Dr. Williams, and Dr. R Shingleton Smith discussed the specimens.—Dr. Stack showed a specimen of Aneurysm of the Internal Carotid Artery at the Base of the Brain from a girl, aged 22 years.—Dr. Fisher showed specimens of Acute Tuberculosis of the Lungs following Tuberculous Peritonitis.—Dr. F. H. Edgeworth read a paper on Transient Renal Hæmorrhage

Davies, medical officer of health of the city and port of Bristol, read a paper on Plague Exclusion and Control. The *simultaneous occurrence among rats of a disease resembling* the plague in man had of late years attracted the attention of epidemiologists who had seen in it an explanation of the spread of epidemics, and at the late International Congress on Tuberculosis this view had been forcibly restated by Dr. R. Koch who insisted on the grave error of attempting to treat all pestilences on the same lines and applying quarantine and disinfection to all indiscriminately instead of combating each as its etiology indicated. The notion that personal contact was the chief factor in the propagation of the plague had been accepted by the international conferences with, as the experience of recent epidemics showed, but little success, since they now knew that it was the pneumonic form only that was often directly communicable. But in every outbreak that had been properly investigated rats had been proved to be the active agents and with their extermination the disease had disappeared. Yet this view, though accepted by all epidemiologists, had been met by the authorities in every country with more or less of passive obstruction, and even the Indian Government had failed to distinguish clearly cause and effect. It was high time that this fact should be generally known and acted on, for otherwise sanitary measures and inoculations were of no avail. Referring to Dr. Ashburton Thompson's report, Dr. Davies said that at Sydney the agency of rats was obvious and indisputable, but nowhere had this precaution been adopted until it was too late. There the plague had been introduced and spread by rats, and the negligible influence of contagion was seen in the fact that the 289 cases were distributed through 276 *houses. A plague "contact" was not one who had been* exposed to infection by plague patients but to plague rats. The regulations of the Local Government Board of November, 1896, were well enough as regards the importation of the disease by infected persons, but they wholly ignored its introduction by means of rats, especially in ships with cargoes of grain or cotton-seed. The first official recognition of the danger arising from the introduction of the plague by rats was the Order of April, 1901, which advised port sanitary authorities to take precautions against the landing of rats from plague ships, and recommended their destruction and the cremation of their bodies without handling. The Order was, however, not compulsory and was applicable only when the existence of the disease on board was established, but it had the effect of strengthening the hands of the authorities. In Bristol they kept a register of infected ports, based on the lists published by the Marine Department of the United States of America, but retaining the names on the list three or four months longer, since such ports were officially declared free when the disease had disappeared among the human population. All such vessels were considered "suspects," though no cases had occurred among the crew, for the disease might be confined to the rats and communicated by them to the labourers who alone handled the cargo. Thousands of infected rats were at present carried from port to port and permitted to infect freely those on shore, a practice as irrational as would be the isolation of every case of hydrophobia in man while troops of rabid dogs were allowed to remain at large. All rats should be destroyed while the ship was empty and others prevented from going on board, the feasibility of this having been proved by Dr Ashburton Thompson in the Australian ports, where all vessels were fumigated while empty and none were allowed to enter a port without a certificate from that of departure. Turkey alone had taken any steps in this direction, but an international agreement only would be really efficacious. The Bristol Chamber of Commerce had carried at the meeting at Nottingham a resolution for the framing of regulations for ridding all ships of rats at infected ports, which, with similar recommendations from port sanitary authorities, from the British Medical Association, and from the Society of Medical Officers of Health, had been forwarded to the Board of Trade, the Local Government Board, and the Shipowners' Association, but by none of these had it been taken seriously. At present they could attack the rats only at the port of arrival, a course obviously less effective than their destruction at the infected port. If the plague were once introduced the measures to be adopted were: (1) provision for the isolation of the sick, though there was little danger except from pneumonic cases; (2) the quarantine of "contacts"—i.e., of persons who had been in contact with plague rats; (3) protective inoculation of those associating with the sick or employed in infected premises; (4) the exclusion of all rats from dwelling-houses by the putting into thorough repair of all old stone sewers, house drains, and yards and basement floors, the latter by the owners and the former by *the sanitary authorities; (5) the resolute extermination of* all rats in ports and warehouses, as was the duty of the authorities in Western Australia; and (6) the cleansing of "verminous" persons. The only "sanitary" measures, in the ordinary sense of the word, that were of any use were the repair of defective drains and the closure of rat-holes.—Dr. Ashburton Thompson (Sydney) insisted on the necessity for an international agreement as to the destruction of rats on board ships from infected ports, since they might be dying from the plague and might carry it from port to port while none of the crew were attacked. The Indian Governments attached the most importance to infected persons and things, the Australian Government to rats, and the result of the application of this view in the suppression of the outbreak at Sydney, the first treated on modern principles, afforded ample justification. Whatever difficulties might be met with in densely peopled insanitary eastern cities, what had been accomplished in the purely English towns of Australia might be so in those of Europe.—Dr. R. A. Farrar (special plague officer with the Government of India) defended the natives of India, maintaining that in their persons they were cleaner than the lower classes of this country. Neither European nor native attendants contracted the disease in the hospitals and the greater susceptibility of the native was in part due to their habit of going barefoot and wearing toe rings. Infection mostly took place through breaches of the skin or abrasions, and thus while inguinal buboes were most frequent, in the women who swept the floor with their hands they were more often axillary. *On board ship* the barefooted lascars should, he thought, be treated as "contacts," though the well-shod European was not. Rats on infected ships, or during epidemics those killed on shore, should be promptly plunged into strong solutions of corrosive sublimate or carbolic acid to destroy the fleas, and he would suggest funnel-shaped, rather than discoid, shields to prevent the passage of rats along the hawsers.—Dr. Herbert Williams (Port of London) entirely agreed with Dr. Davies that the ideal course was the destruction of the rats at the infected port of departure, but *masters of vessels would not take the* trouble and consular certificates were of little worth. In the port of London they had tried burning sulphur and cylinders of compressed sulphur dioxide, but the former was uncertain and the gas tended to imperfect diffusion, so much so that rats in cages six feet from the cylinders had been found alive. Much greater, but not complete, success had been attained with the Clayton Disinfecting Company's apparatus, which impelled the gas by a fan through pipes into the hold, while for disinfection the return air was *passed over burning sulphur. The total* extermination of rats on shore was impracticable, though he understood that at Odessa over a million had been killed recently. The isolation of vessels was beset with difficulties, as was the use of cranes and lighters, to say nothing of gangways, and with every precaution the rats might be landed in cargo. He had seen a hundred escape from a broken cask.—Dr. E W Hope (Liverpool) dwelt on the extreme difficulty of dealing with vessels of 4000 or 5000 tons, in which the rats passed from hold to hold during the fumigation. The Local Government Board might, he thought, inquire into the efficacy of different methods and empower port sanitary authorities to detain rat-infested ships. He had found the American company's apparatus very successful with empty vessels. He could not ignore sanitary measures altogether when he considered the class of persons who in Oporto and, in Glasgow were the first to be attacked, and he believed in the communication of infection from such persons by means of fleas.—Dr. E. Walford (Cardiff) had had but two cases under his observation; one of the patients contracted *the disease in Cardiff, and the other else*where, but each had been attacked while unloading grain-ships, and the former, whose buboes were axillary, had handled dead rats which were proved by bacteriological examination there and in London to have died from plague. He had been successful with the Clayton apparatus, but was well pleased with the work of professional rat-catchers.—Dr. J. Howard-Jones (Newport, Mon.) and some other members and visitors having continued the discussion Dr. Davies replied briefly.

**BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.**—A meeting of this association was held on Jan. 10th, Dr. John Macintyre, F.R.S. Edin., the President, being in the chair.—Dr. Wyatt Wingrave the work done by them in the seventeenth century when the Royal Society was founded, when we read of the contributions of Boyle, Lower, and Mayow to physiological knowledge. Space fails us to deal with other lectures in which the writer traces the further advances made in our knowledge of digestion by Boerhaave, Haller, and Spallanzani; the explanation of the true meaning of respiration which followed the chemical discoveries of Black, Priestley, and Lavoisier; and the older views concerning the processes of the nervous system. We must be content to commend Sir Michael Foster's book, not only to every physiologist and medical man, but to everyone interested in science, as a valuable lesson in the methods of scientific research and a delightful piece of literature.

---

*Text-book of Medicine.* Begun by the late CHARLES HILTON FAGGE, M.D. Completed after his death and since Revised or Re-written by PHILIP HENRY PYE-SMITH, M.D. Lond. Fourth edition. Vol. I. London: J. & A. Churchill. 1901. Pp. 1123 Price 21s.

A REVISION of "Fagge" radical and far-reaching enough to entitle this classic work to compete successfully with the up-to-date and progressive works of present-day medicine naturally conveys to the mind of its admirers a conception of so great a sacrifice of method and tradition that "Fagge" thus resurrected would be "Fagge" no longer. It must, however, be remembered that in the present instance the revision has been undertaken and carried through in no spirit of impious vandalism, but by the same master-hand which created "Fagge" and invented its traditions. Dr. Pye-Smith's paternal conservatism has saved this treasured volume from the heroic treatment which a more modern author catering for the vulgar, hurried needs of the twentieth century student would doubtless have felt constrained to administer. The leisurely style of the original "Fagge," the historical allusions, the etymological notes and references, the quotations from century-old authors, from Celsus, from Hippocrates, from Galen, and a host of others—all of them find a place in the new as in the older editions. Those who learned their medicine when "Fagge" was the only text-book for the student with ambitions. can have no quarrel with Dr. Pye-Smith for perpetuating in his most recent edition the traditions which they love and reverence. But what of the modern student? Will he appreciate. or has he indeed time to appreciate, the refinements and niceties of style or the discursive experiences of what is now practically a past generation of clinical physicians?

At the time of his death in the year 1883 Dr. Fagge left behind him a vast collection of notes and manuscript, collected mainly from Guy's Hospital reports or as the fruit of his own experiences inside and outside the hospital. This work had occupied his best energies for more than 12 years, so that even when Dr. Pye-Smith undertook, at the request of Mrs. Fagge, the Herculean task of editing the proposed volumes, much of the material and its pathological bearings was already in scientific arrear. In spite of the invaluable assistance of the late Dr. J. Cavafy in the earlier editions, and of Dr. J. F. Payne in the one under review, this scientific arrear has never been made completely good. The discursive style which we have already mentioned as being perpetuated in the present volume does not lend itself to the scientific precision which modern pathology and modern nosology demand, and there is repeated evidence throughout the pages of this first volume that a half-hearted attempt to reconcile traditional speculations with newly ascertained facts has brought the continuity of argument to a condition which nearly approaches chaos For instance, the chapter on Inflammation, evidently written and revised up to the standard of current opinion of some six or seven years ago, represents a valuable and accurate account of this pathological process according to the views then held. Within recent years, however, our views on inflammation have undergone radical modification, and as a graceful concession to the modern pathology Dr. Pye-Smith adds a paragraph at the end of this chapter which not only casts doubt upon the soundness of the views expressed in the previous 20 pages, but practically nullifies everything which depends on the definition of the term "inflammation" as accepted by him and stated at the commencement of the chapter. Seeing how large is the part which inflammation plays in the pathology of diseases dealt with in this volume, it is unsatisfactory, to say the least, that the foundation should be beset with these ambiguities. The distinction between degenerative changes and inflammatory processes is admittedly a matter of great difficulty, and in no department of medicine is this more apparent than in that of diseases of the central and peripheral nervous systems. Here, again, we cannot admit that Dr. Pye-Smith has always made the position clear. And in this connexion we would quote two passages in different sections of the volume which, if not absolutely contradictory, at least present a confliction of views. Referring to the lightning pains of tabes on page 560 Dr. Pye-Smith says: "In all their characters they are true neuralgias and they are not due to demonstrable lesion of the nerves," while on page 700 in the same connexion he says: "The peripheral afferent nerve-trunks, as well as their roots, are affected; ...... the boring and flashing pains, no doubt, are caused by morbid changes in the posterior root-zones."

Although, as we are told in the preface, at the present time there is scarcely a page of the late Dr. Fagge's work as he left it at the time of his death, nevertheless the passages which deal with the anatomy of enteric fever, the clinical account of variola and scarlet fever, the course of malarial fever, the description of neuralgia and migraine and of epilepsy and bronchitis appear very much as they were presented in former editions. The introductory sections on general pathology and those on diabetes, rheumatism, osteoarthritis, diphtheria, tabes dorsalis, and several others have been completely re-written for the present volume.

The chapters on Gout, Beri-Beri, Rickets, and, we may add, Rheumatism, including as they do departments of medicine in which much new work has been published and many theories have been expressed, will strike the reader as pedantically old-fashioned for a modern text-book. For instance, as regards gout we may question whether "the primary fact" to be kept in mind in considering this disease is the excess of urates in the blood. On this pathological pivot, however, the symptoms, morbid anatomy, and etiology are almost entirely explained. The definition of gout as a disease characterised by the deposition of insoluble urates in the cartilages of joints and subcutaneous tissues is narrow enough in all conscience to exclude bronchitis, dyspepsia, gastralgia, iritis, cystitis, urethritis, phlebitis, and eczema from the list of symptoms and manifestations often included among the syndromata of the *gouty diathesis. At a period of medical history when* the deposition of insoluble urates is generally regarded as one of the manifestations, and not the essence, of gout this careful differentiation of what are usually held to be associated symptoms from the primary disorder is dogma of a most pronounced type.

In reference to rheumatism, which is defined as an acute febrile disorder running an undefined course with implication of the joints and often of the heart, Dr. Pye-Smith does not declare in favour of a specific origin. At the same time he hesitates to associate it with the arthritic diathesis or the disorders of metabolism. In adopting a somewhat *non-possumus* attitude towards every theory which has so far been suggested he leaves the reader in a condition of nebulous speculation. The short chapter on beri-beri leaves the reader in a similar condition of doubt, as may be inferred due to Chill.—Dr. Wills, Mr. Roger Williams, Dr. Williams, Mr. J. Taylor, Dr. Smith, Dr. Stack, Dr. Clarke, Dr. Skerritt, and Dr. Harrison discussed the paper.—Dr. J. Odery Symes read a paper on Some Urinary Infections, with special reference to their Treatment by Urotropin.—Mr. T. Carwardine, Dr. Fisher, Dr. Neild, Dr. Cave, Dr. Stack, Dr. Edgeworth, and Dr. Harrison spoke on the paper.—Dr D. S. Davies gave a short report on a recent case of Black Small-pox in Bristol.

**Liverpool Medical Institution.**—At the annual meeting of this institution held on Jan. 9th the following office-bearers, members of council, and committees were elected:—President: Mr. Rushton Parker. Vice-Presidents: Dr. Edward Adam, Dr. J. M. Hunt, Dr. John E. Gemmell, and Dr. W. Permewan. Honorary treasurer: Dr. H. Briggs. Honorary general secretary: Dr. J. R. Logan. Honorary secretary to ordinary meetings: Dr. J. Hill Abram. Honorary librarian: Dr. Leslie Roberts. Council: Dr. James Barr, Dr. R. J. M. Buchanan, Mr. G. A. Hawkins-Ambler, Dr. W. Macvie, Dr. E. Nicholson, Dr. J. Lloyd Roberts, Mr. Edgar A. Browne, Dr W. M. Cairns, Dr. D. Douglas-Crawford, Dr. J. Ernest Nevins, Professor C. S. Sherrington, and Dr. W. B. Warrington. Pathological and Microscopical Committee: Professor R. W. Boyce, Mr. R. A. Bickersteth, Dr. R J. M Buchanan, Dr. D. Douglas-Crawford, Dr. John Hay, Dr. O. J. Macalister, Mr. K. W. Monsarrat, Mr. G. P. Newbolt, Professor Sherrington, and Dr. Warrington. Journal Committee: the honorary secretary to ordinary meetings, the honorary secretary of the pathological section, Dr. F. H. Barendt, Mr. F. C Larkin, Mr. Newbolt, Professor A M. Paterson, Mr. W Thelwall Thomas, Dr. Arthur J. Wallace, and Dr. Permewan. Auditors: Dr. J. Lloyd Roberts and Dr. Dawson.

**British Electro-Therapeutic Society.**—A meeting of this society was held on Jan. 10th, Dr. W. S. Hedley being in the chair, at which a list of 58 medical men was read as constituting the members of the above society. The rules suggested by the provisional committee were discussed and the majority of them passed A few amendments and additions are to be brought forward for confirmation at the next meeting on Feb. 14th. The following officers were then elected:—President: Dr. W. S. Hedley. Vice-Presidents: Dr. Lewis Jones and Dr. H. G. Turney. Council: Dr. A. Barry Blacker, Dr. Wilfred J. Harris, Dr. George Herschell, Dr. Septimus P. Sunderland, Dr. Hugh Walsham, Mr. William Armstrong, Dr. J. Allan, Dr. James Barr, Mr. J. F. Hall-Edwards, Dr. Robert Jones, and Dr. Ernest Solly, with power to add to their number. Honorary treasurer: Dr. H. McClure. Honorary London secretary: Mr. Chisholm Williams. The annual subscription is one guinea and there will be eight meetings in the year. A journal will be published quarterly. Medical men desirous of joining should send their names to the honorary secretary, 20, Bedford-square, London, W.C.

**The Royal Institution.**—In the fifth of his Christmas lectures on Waves and Ripples, delivered on Jan. 7th, Professor J A. Fleming dealt with the subject of electric oscillations and electric waves. He described the production of Hertzian waves and said that the essential principle of the coherer had been discovered by several persons. Professor Hughes observed a phenomenon of this kind in 1879 or 1880. It was afterwards found that the apparatus was rendered more sensitive by substituting metallic filings for the discs previously used, and one form of the instrument used by Marconi in his wireless telegraphy was constructed on this system. In the sixth and concluding lecture, delivered on Jan. 9th, Professor Fleming said that electric waves could be refracted by metal plates and could be brought to a focus by lenses of paraffin wax, just as light was brought to a focus by glass lenses Water was opaque to electric waves, but they could be refracted by a prism of ice provided that its surface was perfectly dry. The various classes of waves in the ether might be considered as forming a sort of gamut or scale, having at one end (that with the shortest wave-lengths) invisible but chemically actinic ultra-violet rays, then the luminous spectrum, then the rays of dark heat beyond the red end of the spectrum, followed at a considerable interval by Hertzian or electric waves of different lengths.

# Reviews and Notices of Books.

*Lectures on the History of Physiology during the Sixteenth, Seventeenth, and Eighteenth Centuries.* By Sir MICHAEL FOSTER, K.C.B., M.P., M.D. Lond., D.C.L., &c. (Cambridge Natural Science Manuals.) Cambridge: The University Press 1901. Pp. 310. Price 9*s*.

IT is probable that there is no one man so well fitted as is Sir Michael Foster to write the history of the subject which has made his name familiar to physiologists all over the world. No epoch-making discovery, no special line of research, is associated with his name, but by general consent he knows physiology as few others know it. We are therefore not disappointed, on turning over these pages, to find a luminous criticism of the physiology of the past and an instructive lesson in the methods by which our present knowledge has been attained—a lesson not confined to physiology but applicable to every department of science. It is, indeed, the history of scientific progress in general with which Sir Michael Foster is compelled to deal in his lectures. The history of physiology is so closely interwoven with the histories of anatomy, chemistry, and physics that they cannot be considered apart. Pathology and medicine are so intimately based on physiology that these lectures give us their earlier history too The broad general lesson conveyed is that the one method which has ever yielded solid and lasting result is that of faithful observation and thoughtful experiment.

The lectures here printed were delivered in San Francisco in 1900 They represent an amount of research and learning which have extended over many years of the writer's life There is no attempt to cover the whole history of physiology even within the limits of the three centuries under consideration. The plan followed is that of selecting certain branches of the subject, such as circulation, digestion, and respiration amongst others, and dealing with them very fully. Each branch is naturally associated with the names of those great pioneers who laid the foundations of our knowledge concerning it, and biography is pleasantly mingled with history. The result is something far more engrossing and delightful than the dry bones of history alone, and if only for this reason something much more instructive. We gain a living picture of those far-off workers and are enabled to form an idea of their mental attitude towards the problems which confronted them. To say this is to give the highest praise which can be bestowed upon a scientific historian. It is easy to chronicle discoveries and their dates and to prove that someone stole the ideas of somebody else, but to enable the reader to stand, as it were, in the shoes of Vesalius, Harvey, or Van Helmont, and to limit his scientific conceptions within their narrower purview, and to grope with them into the darkness, is an achievement of no common order, and it is this which Sir Michael Foster has succeeded in doing.

Commencing with the life and times of Vesalius we read how this great observer laid the foundations of modern anatomy—the first effective revolt against a blind adherence to tradition We follow the influence of his teaching and learn how it led up, through Cæsalpinus, Fabricius, and others, to Harvey's great discovery. We read of the rise of modern physics and of how in the hands of Borelli many physiological problems received a physical explanation. We learn how Malpighi founded the science of histology and how our ideas of glandular secretion took origin. The rise of chemical physiology from the days of Paracelsus, through those of Van Helmont, Sylvius, and Stahl, is dealt with in two chapters in which the physiology of digestion takes an important place. We may well be proud of the share taken by Englishmen in the development of natural science and of cast up on the shore of his native county, "it was to rake for ambergriese in the paunch of this leviathan, as Greenland discoverers and attests of experience dictate that they sometimes swallow great lumps thereof in the sea—insufferable fetor denying that inquiry." Olaus Magnus, the Archbishop of Upsala, thought ambergris a good specific for syncope and epilepsy. M. Beauregard declines to recommend it for anything except as a doubtful aphrodisiac. A remarkable instance of a drug which has apparently persisted from primitive pharmacopœias to the present day is afforded by the common river crayfish. In the stomach of that creature are certain slimy concretions known as gastroliths. Such a structure, not always present in the animal and of rather mysterious import in its economy, is precisely the kind of thing that the mediæval physician would set great store by. These gastroliths or "crab's eyes," as the more vernacular term runs, are still pounded up and mingled with various powders which are referred to by M. Beauregard. It is not until we get quite near to the end of the book that the author grapples with an animal product which is really of use and which has been investigated chemically, physiologically, and therapeutically. This substance is cantharidine, formed from various species of beetles; these beetles are represented in two excellent coloured plates.

We have attempted to give some notion of the contents of this volume. It has most emphatically interested us in its perusal and will certainly interest others. Whether it is wanted, in the grosser utilitarian sense, is another matter altogether.

---

*The Criminal.* By HAVELOCK ELLIS. Third Edition, Revised and Enlarged, with 40 Illustrations. London: Walter Scott. 1901. The Contemporary Science Series.

IN this volume the author has made an attempt to present to the English reader a critical summary of the results of the science now commonly called criminal anthropology. We have perused the book with considerable interest and can recommend it to those who wish for information on a difficult subject considered both from a scientific and a social point of view. That the work has reached a third edition is evidence that it has supplied a want.

Mr. Ellis points out that the great question which the criminal anthropologist has to answer is, "What is a criminal? Is he—according to the old legal assumption on which our criminal law is still mainly built up—a normal person who has wilfully committed an abnormal act? Is he the victim of acquired disease, such as some form of epilepsy? Is he an atavistic reappearance of the savage in modern society? Is he a 'degenerate'?" Mr. Ellis discusses these matters in an intelligible and attractive manner. He believes that the criminal, in some of his most characteristic manifestations, is a congenitally weak-minded person whose abnormality, while by no means leaving the mental aptitudes absolutely unimpaired, chiefly affects the feelings and volition, so influencing conduct and rendering him an anti-social element in society. The criminal, according to the author, is in a majority of cases certainly not insane, but neither is he normal, and while not wholly insensitive to the motives which influence the normal man he is not affected by them in the same way or in the same degree as the normal man.

The chapters on the physical and psychical sides of criminal anthropology are well written and contain much that is interesting. The question of the treatment of criminals is a difficult one. Mr. Ellis has much to say on the subject, although we must admit that we derived but little profit after reading his remarks, and many able observers are studying the matter critically and carefully. The various methods adopted in different countries seem to give much about the same results, and doubtless the time will come when the investigations now being carried out will bear fruit. The better housing of the working classes, for instance, must have a great influence on criminality. "The worker," says Professor Prins, "is always on the borders of vagabondage; the vagabond is always on the borders of crime." If the stress of misery could be generally decreased the number of criminals would likewise become less. Social organisation is the basis upon which any criminal reform must be formed.

*Lehrbuch der Speciellen Pathologischen Anatomie.* Von Dr. JOHANNES ORTH, Ord. Professor der Allgemeinen Pathologie in Göttingen. Neunte Lieferung: Auge, bearbeitet von Professor GREEFF. 1. Hälfte, mit 2 lithographirten Tafeln und 76 Abbildungen im Text. (*Text-book of Special Pathological Anatomy.* By Professor JOHANNES ORTH. Ninth Part: The Eye. By Professor RICHARD GREEFF. First half, with two Lithographed Plates and 76 Figures in the text.) Berlin: Hirschwald. 1902. Pp. 270. Price 7 marks.

THE present instalment of Professor Greeff's useful work is divided into five chapters which deal in succession with the Conjunctiva, the Cornea, the Sclera, the Iris, and the Ciliary Body. The account of the conjunctiva naturally commences with a very careful description of the epithelium in the different regions of the conjunctival sac. These regions he distinguishes as the anterior or palpebral area and the bulbar or posterior area, a division that is of great importance from a pathological point of view, for lymphoma or follicles only affect the anterior region which presents columnar epithelium like mucous membranes, whilst cutaneous diseases, as, for example, eczema, which appear in the form of phlyctenulæ on the conjunctiva bulbi, only appear on that region which is covered with laminated pavement epithelium, and consequently resembles the skin in structure. The columnar cells of the anterior region are arranged in two rows, of which the deeper one is flatter than the superficial one, and intermediately lying cells may be occasionally observed. The pavement epithelium of the posterior region presents a deep columnar layer of small cells which are continuous with the much larger columnar cells of the cornea, a middle layer of numerous polygonal cells with central nucleus, and a superficial layer consisting of one or two flattened cells. Intervening here and there amongst the latter two sets of cells, at first deeply situated, but subsequently near the surface, are scattered goblet cells, which the editor has satisfied himself are, as L. Green contended, unicellular mucous glands, of great importance in the functions of the conjunctiva. Lastly, there are a few leucocytes. The mucous layer of the conjunctiva is divisible into two layers—a superficial or adenoid layer and a deep or fibrous layer. The adenoid layer contains many lymph cells which move about in it with ease and sometimes form small balls which, with von Recklinghausen, he names lymphatic follicles, but doubts whether they are to be regarded as normal elements of the conjunctiva. This layer presents some feebly developed papillæ and is highly vascular, but the fibrous layer contains the majority of the vessels and nerves. The conjunctiva palpebrarum contains the acino-tubular glands named after Krause, of which there are about 40 in the upper and about six or eight in the lower lid. These ducts open at the conjunctiva fornicis. Besides these, Stieda's grooves and ridges are to be noted, which, as Rählmann has shown, first appear two or three months after birth, and are to be found most developed at the line of reflection of the membrane; and, finally, the simple follicular glands of Henle. Proceeding from these anatomical data Professor Greeff describes very precisely the different forms of conjunctival inflammation, and names them according to their etiology, illustrating the statements in the from the following sentence: "The pathology of beri-beri is uncertain; it is certainly not a form of malaria nor of scurvy, nor it is caused by any poisonous food; it does not depend on the presence of animal parasites." The article on rickets, unlike that on gout, is founded on a much broader pathology and contains an unusually full account of the methods of treatment. The following quotation is not, however, suggestive of modern methods: "When a feeding-bottle is used the most extreme care is required to keep it and its tube clean" It is unfortunately too often true that "tubes" and rickets are found associated in the same nurseries, but that "tubes" should be seriously discussed in a modern text-book which is for the instruction of the coming generation of practitioners is, to say the least, disappointing.

Up to this point we have taken the obvious line of criticism which on general grounds would suggest itself to a reviewer who has to deal with a text-book which first saw light nearly 20 years ago and is now for the fourth time published under the same editorship and under an editorship which is single-handed and self-reliant. There is, however, an altogether different standpoint from which this new edition may be approached, and many serious students will no doubt regard it in this view—namely, that the art of drawing accurate and striking pictures of disease, an art of which each succeeding edition of "Fagge" has given more brilliant and speaking examples, is so rapidly disappearing that it is the positive duty of those older clinicians who still retain this facility of description to give the world the benefit of their skill. Fagge's Medicine is, so far as we know, the only text-book of its kind which at the present day presents the clinical aspect of disease in a style which Sydenham, that great master of descriptive medicine, would have approved. For this reason if for no other, we, as a nation and as a profession, owe Dr. Pye-Smith a debt of gratitude, for with untiring efforts he has remodelled for contemporary use perhaps the greatest text-book of clinical medicine which has ever been published in any language.

---

*Matière Médicale Zoologique: Histoire des Drogues d'Origine Animale.* Par H. BEAUREGARD. Revisé par M. COUTIÈRE, avec Préface de M. D'ARSONVAL. Paris: G. Naud. 1901. 8vo. Pp. 396 With five Plates and 145 Figures in the text. Price 12 francs.

THIS work is a comprehensive treatise upon those animals whose products are, or were recently, used in pharmacy. But it is not limited to a disquisition upon the drugs themselves and upon the animals and organs whence they are extracted; the author, who unfortunately did not survive to see his work in print, gives also the generalities of the several groups, orders, and families of the animal kingdom the members of which have provided mankind with drugs. The treatise, in fact, is one upon general zoology so far as concerns the main sub-division of the animal kingdom. It is accompanied by abundant illustrations of outward form and internal structure, with naturally a special prominence given to the anatomy and histology of those glands whence the drugs are derived. It will astonish the non-expert to observe how many different kinds of animals contribute to the healing of man's infirmities The list is not perhaps so long as was that of a mediæval physician in Europe or a Chinese doctor of to-day; but it is by no means short. Altogether some 50 kinds of animals figure in M. Beauregard's list, and of these the majority are mammals. Next in numbers are insects, fishes come third, while reptiles, crustacea, worms, and sponges furnish but one or two representatives each of creatures whose flesh or skeletons provide drugs While viverreum (the product of civets and genets), castoreum (derived from the beaver), and hyraceum (really the excrement of the hyrax) are no longer used in medicine, the musk of the musk-deer is still, though rarely, given as a drug in cases of "intense general depression." But in this and the other secretions already referred to the physiological action has not been studied. It is, after all, much on the same level with the recently reputed cure for cancer in the shape of violets. M. Beauregard gives, in fact, an example of a drug which has this kind of reputation. It was asserted that the hoofs of the elk were "efficacious as a remedy for epilepsy." This example brings us to the consideration of M. Beauregard's selection of drugs. It is not quite clear why he includes such an instance as that which has just been given and why he excludes many of the mediæval and subsequent remedies. The ancients used anything and everything that they could lay their hands upon for the cure of sickness, and the late use of some of the substances referred to by M. Beauregard is possibly to be explained as a survival from antiquity. That unconsciously humorous divine and natural historian, the Rev. Edward Topsell, observed that "the beastes do offer many profitable medecines for the cure of men; which the skilful Physitian must borrow from them if he will be perfect in his art and conscionable in his profession." And he goes on to remark: "I have proved by the inspection of this knowledge that herein is layed the largest foundation of Medicine." If M. Beauregard includes the hoofs of an elk and bezoar stones, why should not he also tell us something about the oil in which a fox is baked alive or dead, "the dust of a living Weasell brent," "a fat cat sod" (whatever that may be), and, especially at the present moment, a shaving of a goat skin mixed with pumice stone and vinegar, which is good for the small-pox? The author seems to us, in fact, to have hesitated midway between alternative modes of dealing with his subject. He should either have given us a large amount of antiquarian drug lore, or resolutely cut out all such animal products as are not used at the present moment in civilised countries. We wonder if many of the readers of the present notice have ever heard of "Ægagropiles"; the term is new, though the objects to which it is given as a name are probably familiar to most persons. An ægagropile is an expression used for those felted balls of hair that are found in the stomachs of many animals, particularly ruminants. They are mentioned by the author in the type which he uses to embody the names of drugs, but no suggestion is made by him as to their present or past use in the Pharmacopœia When we get to the subject of pepsine we tread on firmer ground, though whether the use of artificial digestives of this kind can be fairly termed drugs is perhaps a matter for argument. Pepsine is, according to the author, especially made from the stomachs of sheep. One of the most interesting of M Beauregard's chapters is that dealing with spermaceti As a drug its use is mentioned for the first time in the pharmacopœia of the University of Salerno—the same university which addressed a versified series of remedies to Robert, "King of England." But the Salernites, as the author calls them, confused spermaceti with ambergris, and this confusion, initiated by those well-meaning but officious savants, lasted until the sixteenth century. We have now fully unravelled the complications, and spermaceti, it is perhaps unnecessary to explain, is the fat contained in the great head of the cachalot, while ambergris is a pathological product of its liver which is now used mainly as a vehicle for perfumes, though it possesses a sweet, earthy smell of its own. Sir Thomas Browne, who is not quoted by M. Beauregard, was one of those physicians who was not by any means in advance of his time His full belief in witchcraft is well known and the consequent cruelties which he condoned. His intelligence in the matter of ambergris was not much better, as the following observation—which, perhaps, we may be allowed to quote—shows: "In vain," he wrote of a sperm whale first deals with the diagnosis and treatment of the various forms of gall-stone disease. The author lays great stress on an accurate history, and he claims that the diagnosis may be made often merely on the history, and that even if this be not possible the physical examination is greatly simplified by a complete history. This part dealing with the diagnosis is especially good. The author agrees with most surgeons in condemning exploratory punctures; for, as he points out, even without fever pus may be present Professor Kehr has not much opinion of the value of examination under anæsthesia, for he thinks that much more may be learnt from the history. The second part consists of notes of 100 cases of cholelithiasis in which the author has operated. They have been chosen to illustrate the chief points in diagnosis. They will well repay perusal, even though the reader may not always coincide with the author's opinion or treatment. An appendix give notes of 18 additional laparotomies for cholelithiasis which the author had performed in a little more than six weeks. This statement will serve to show the large number of cases on which he operates The translation is very accurate—in fact, too accurate, for it follows the original so closely that we find German phrases in English words. The peculiarity of the style is in great part due to Professor Kehr, but the translator might reasonably have modified it. Some of the sentences are almost cryptic, though the meaning can be found by a little thought We may quote the following as a specimen: "Adhesive peritonitis in the gall-bladder is such an exquisite human disease that I am inclined more to traumatic influences than stones." In spite of these criticisms we may repeat that Dr. Seymour has conferred a benefit on those surgeons who do not know German by translating this book into English.

# New Inventions.

## FORMALDEHYDE LAMP.

THE experiment of wrapping round the wick of a spirit lamp a spiral of thin platinum wire by which after the flame has been blown out partial combustion is kept up, aldehyde being given off, is a familiar one By substituting pure methyl alcohol for ordinary spirit formaldehyde is obtained, and on this principle a steady current of the powerfully antiseptic gas may be produced At the same time water is a product of the change and a moist environment is essential to germicidal action. At any rate this principle is applied with some success in a lamp which we have recently received. It consists of a glass reservoir containing methyl alcohol in which a cotton wick serves to keep two discs of platinum black supplied with the spirit To start the lamp a light is applied and the spirit is allowed to burn for some minutes until the platinum gets quite hot. The flame is then blown out when it will be found that at certain points the platinum glows feebly and formaldehyde vapour is steadily given off. According to our laboratory experience the lamp works well and without any special trouble. The method seems to be extremely convenient and useful for the diffusion of formaldehyde, one of the most powerful germicides for the purpose, in the air of infected rooms The lamp is easily kept under control, the quantity of formaldehyde given off being determined by the amount of methyl alcohol consumed. The action of the lamp is stopped by replacing a screw stopper which covers the platinum cap. The lamp is the invention of a medical man in Paris and the agent for its sale in this country is Mr. H. M. Kelly of 10, St. Mary Axe, London, E C.

## HOSPITAL REPORTS.

### GUY'S HOSPITAL.

JAN. 16.

*Amputation at the Hip Joint.*

This formidable operation was performed here this morning, for the first time, by Sir Astley Cooper in the presence of some of the surgeons and pupils belonging to these institutions. The number of those present however, was not so great as on many other occasions, no previous notice of the operation having been given, and this arose in consequence of it not having been determined on but a few minutes before its performance. The patient was a man about forty years of age, whose thigh had been amputated some years ago, just below the knee, since that time the thigh bone had become diseased from the extremity of the stumps, up to the trochanter major; and this disease has had such effects on him of late, that he has been rapidly sinking under it; the thigh was of the middle size; on being asked this morning to submit to an operation, he readily consented. At half-past-one the patient was brought into the operating theatre, and placed in the recumbent posture on the table; the femoral artery, being tightly compressed at the groin by an assistant, (Mr. Key), Sir Astley, standing to the outer side, with the limb in the one hand, and the catlin[1] in the other, commenced the operation, by making an incision just below Poupart's ligament, a little to the iliac side of the femoral artery; this was continued obliquely downwards and outwards to the back of the thigh, about one-third of the way down, from which point the knife was carried in the opposite direction, obliquely upwards and inwards to meet the first incision, by this means, forming an eliptical curve; at this step of the operation, the femoral artery was divided, to which a ligature was immediately applied; the cellular membrane was merely cut through at first, but the knife was again carried in the same direction as before, and thus the muscles were also separated; at this step also, it was necessary to apply another ligature on the inside of the limb; here the operator changed positions, and sat on a chair in front of the patient, and waited a short time to see whether there were any bleeding vessels; after the lapse of a few minutes the operation was continued and very shortly completed, the head of the thigh-bone being removed from the acetabulum without any difficulty; two ligatures in addition to those already used were applied, making in the whole four; the integuments were brought together, and a suture applied to the upper portion; strips of adhesive plaster, and lastly a bandage were put over the stump. There were about 12 ounces of blood lost, but it had the appearance of being venous The limb was removed in the space of twenty minutes, the securing the arteries and dressing occupied fifteen more; the whole was completed in thirty-five minutes. During the operation the man was extremely faint, but some wine being given him, and fresh air admitted, he recovered. The patient bore the operation with extraordinary fortitude, and after all was finished, he said to Sir Astley, "that it was the hardest day's work he had ever gone through," to which Sir Astley replied, "that it was almost the hardest he ever had."

---

[1] It may not be unnecessary to explain to the younger generation of our readers that a catlin was a long, narrow, double edged knife used for amputations.—ED L.

WELLS (SOMERSET) DISPENSARY.—The annual meeting of the subscribers to this institution was held on Jan. 7th, under the presidency of the Mayor. The financial statement showed a favourable balance. After some discussion it was decided to discontinue the dispensary on its present basis as a charity, and a committee was appointed to report upon the best means of forming a dispensary on provident lines.

text with good woodcuts. Thus he differentiates the pneumococcus of Fränkel-Weichselbaum as the cause of one form of conjunctivitis, the Morax-Axenfeld diplo-bacillus as that of another, the Koch-Weeks bacillus as that of a third, and the streptococcus as that of a fourth; the gonococcus of Neisser and the Klebs-Löffler bacillus of diphtheria complete the list. The characters of each of these infectious agents are described in full detail. A coloured plate with the explanatory text shows the characters of conjunctivitis trachomatosa or trachoma. The differing and to some extent incompatible views of J. Müller, Eble, Duvillard, Himly, Berlin and Iwanoff, Leber, Saemisch, Sattler, Rählmann, and several others who have occupied themselves with the pathological characters of trachoma are given. Professor Greeff describes the trachoma follicle as sharply-defined nests or knots of cells lying in the adenoid tissue of the conjunctiva. Blood-vessels penetrate into the mass, which is traversed by a connective tissue framework with fixed connective tissue cells, the whole invested by a feebly developed connective tissue capsule which he depicts. The cells inclosed by the capsule present great variations, lymphocytes, mononuclear and polynuclear leucocytes, phagocytes, and giant-cells being found.

The changes that occur up to the period of cicatrisation are very instructively given. Professor Greeff will in no wise admit the division so often met with in books of follicular and papillary and mixed trachoma. He considers that the infectious agent or bacillus has not been discovered, but he has no doubt of its existence. The author then describes the microscopical features of various forms of conjunctivitis, as of C. veralis; C. petrificans; C. nodosa, or pseudo-tuberculous conjunctivitis; xerosis conjunctivæ with its bacilli; pemphigus; amyloid degeneration of the conjunctiva; and various tumours of that membrane, as sarcoma, papilloma, adenoma, fibroma, angioma, and cysts, are carefully and fully described in succession.

We have only here given the mode in which the conjunctiva is treated by Professor Greeff and it will be seen how full and instructive his treatise is, but we hasten to add that the pathological conditions of the cornea, sclera, iris, and corpus ciliare are equally well given and that since the appearance of Pagenstecher's "Atlas" no work has equalled it. It will be studied by all ophthalmic surgeons and constitutes a very important addition to our knowledge of the pathology of the eye. We trust that the second part will soon make its appearance.

*A Treatise on Surgery by American Authors for Students and Practitioners of Surgery and Medicine.* Edited by ROSWELL PARK, A.M., M.D., Professor of the Principles and Practice of Surgery and of Clinical Surgery in the Medical Department of the University of Buffalo, &c. Condensed edition, with revisions. With 625 Engravings and 37 full-page Plates in colours and monochrome. London: Henry Kimpton. 1901. Pp. 1262. Price 25*s.* net.

THE valuable treatise on Surgery edited by Dr. Roswell Park and published a few years ago achieved the success which it deserved. It was felt, however, that it was rather large and expensive for the average practitioner or student, and therefore it was decided to issue a smaller edition, while at the same time the opportunity has been taken of revising numerous points In its present form we may apply practically all the remarks that we made on the original edition in 1898,[1] when we reviewed the work very fully. The chief effect of the contraction of the size of the treatise has been to make it more readable and more handy in use. It is certainly now more fitted for the use of students.

It is natural that we should look to see if any of the points to which we drew attention in reviewing the original edition have been altered. Unfortunately, they have received no notice. We still find "Lister's long splint" when it should be "Liston's"; Celsus is still described as the "prince of Greek physicians," although he lived in Italy and wrote in Latin; and still no mention is made of the value of potassium iodide in the treatment of actinomycosis in the general account of that disease. Of course, these are small points, but it would be well to correct them before another edition appears.

We must also draw the attention of the editor of the work to the statement that "fibrin is produced by the union of two substances, known as fibrinogen and paraglobulin." For many years it has been recognised that paraglobulin has nothing to do with the formation of fibrin.

## LIBRARY TABLE.

*Phototherapy: (1) The Chemical Rays of Light and Small-pox; (2) Light as a Stimulant; (3) The Treatment of Lupus Vulgaris by Concentrated Chemical Rays.* By Professor NIELS R. FINSEN of Copenhagen. Translated from the German edition and with an Appendix on the Light Treatment of Lupus by JAMES H. SEQUEIRA, M.D., M.R.C.P. Lond., Dermatological Assistant and Medical Officer in Charge of the Light Department at the London Hospital; Physician to the North-Eastern Hospital for Children. London: Edwin Arnold. 1901. Pp. 79. Price 4*s.* 6*d.*—The three articles on the Action of Light in Disease, which are here presented in an English dress, are recognised as very valuable contributions to the study of a subject which had been greatly neglected by physicians. That light affected the pustulation in small-pox, and that by limiting the light of the sick-room to the red rays the severity of the disease could be mitigated, was held more than two centuries ago, though comparatively recently the idea was ridiculed. Professor Finsen's investigations into the effect of light on small-pox placed the subject on a definite experimental basis. He showed that if only red light be allowed access to the patient the vesicles do not, as a rule, enter upon the stage of suppuration and that hardly any scarring results. This investigation also included a study of the effects, macroscopic and microscopic, of light on the skin, and valuable results were obtained. The second article originally appeared in 1895, and deals with Light as a Stimulant. Professor Finsen made many experiments on the effect of rays of different colours on some of the lower forms of life and found that the chemical rays seemed much more exciting than the red rays; the chemical rays stimulated these animals, tadpoles, beetles, worms, and salamanders, to movement, while they came to rest when only red rays acted on them. The last essay is on the Treatment of Lupus by Concentrated Chemical Rays. The material of this paper has been presented to English readers several times in abstracts and therefore we need say little about it. It will be convenient for many to have a full account of it in English. Dr Sequeira has written a useful appendix which consists of a *résumé* of a paper by Dr. Forchhammer who is in charge of the clinic at the Finsen Light Institute at Copenhagen. This paper brings the subject up-to-date.

*Introduction to the Differential Diagnosis of the Separate Forms of Gall-stone Disease, based upon his own Experience gained in 433 Laparotomies for Gall-stones.* By Professor HANS KEHR of Halberstadt. Authorised translation by WILLIAM WOTKYNS SEYMOUR, A.B. Yale, M.D. Harvard, formerly Professor of Gynæcology in the University of Vermont, &c. With an Introduction by Professor KEHR. London: H. Kimpton. 1901. Pp. 370. Price 9*s.* net.—An experience founded on more than 400 operations for gall-stones cannot fail to be of interest to all surgeons, and therefore Dr. Seymour has done well to introduce this work to the English-speaking peoples, among whom it was hardly known. The book consists of two parts. The

# APPLICATION FORM.

## *To the Almoners of the Lancet Relief Fund.*

The applicant should here state shortly :—

1. The nature of the emergency that has arisen.

______________________________

______________________________

______________________________

2. The circumstances out of which it has arisen.

______________________________

______________________________

______________________________

3. The amount of the grant desired, and whether by way of loan (free of interest) or of gift.

______________________________

______________________________

______________________________

4. If by way of loan, state when the loan will be repaid; and from what source the funds to repay it are expected to be forthcoming.

______________________________

# THE LANCET RELIEF FUND.

*For Members of the Medical Profession and their Widows and Orphans when in Distress.*

———:0:———

## ALMONERS.

THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.
THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.
THE PRESIDENT OF THE GENERAL MEDICAL COUNCIL.
THOMAS WAKLEY, F.R.C.S. Eng.
THOMAS WAKLEY, Jun., L.R.C.P. Lond.

## HON. AUDITOR.

SIR HENRY PITMAN, M.D. Camb., F.R.C.P.

———:0:———

THIS FUND will be provided year by year in the month of January to the amount of at least £300 solely by the Proprietors of THE LANCET, and administered free of cost, for the purpose of affording immediate pecuniary assistance to Medical Men, or their Widows and Orphans, *in cases of Acute Distress and Emergency*, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require.

Applicants must satisfy the Almoners of the Fund that they are qualified under the following regulation:—

> *"The recipients shall be such persons as satisfy the Almoners that they possess one or other of the following qualifications—that is to say: (*a*) That the applicant holds a registered medical qualification, and that he has fallen into pressing need of immediate pecuniary relief; or (*b*) That they are persons who have been, previously to the date of application, legitimately dependent upon some person holding a registered medical qualification, and that they have pressing need of immediate pecuniary relief."
>
> *(In the case of Widows and Orphans, in order to come within the scope of the Fund, the death of the Husband or Father must have been of recent occurrence.)*

To ensure the utmost despatch, the "Application Form" upon the other side should be filled up and forwarded (in an envelope superscribed "THE LANCET Relief Fund") to the Secretary, Mr. CHARLES GOOD, THE LANCET Offices, Strand, London, W.C.

The application *must* be accompanied by two separate Testimonials (originals, not copies)—one from the Clergyman of the Parish or other resident Minister of religion, and one from a registered Medical Practitioner. Each Testimonial *must* state—(1) that the application addressed to the Almoners has been read; (2) how long the writer has known the applicant; (3) that the writer believes the statements made by the applicant to be perfectly truthful, and such as may be acted upon without further inquiry; and (4) *may* state any other particulars that the writer desires to place before the Almoners.

Testimonials written for the Almoners of the Fund will in no case be returned.

*No.* ____________

metropolis. For not only are the London theatres visited by thousands of persons yearly from every part of the United Kingdom and from abroad, but regulations which are enforced for the safety of playgoers in London are likely to be quickly imitated in our other great towns. This question is one in which THE LANCET must necessarily take a keen interest, since we have always felt that nothing which affects the health or the safety of the public can possibly be indifferent to us. Of course, a vast improvement in respect of safety has taken place in all English theatres, and, indeed, in theatres all over the world, during the last 20 years. Playhouses are more scientifically constructed. Party walls of great thickness between stage and auditorium and the presence of firemen behind the scenes are now insisted on. The importance of isolated sites wherever possible for such buildings is widely recognised. Fire-proof curtains are in general use, while the introduction of electric lighting, more particularly behind the scenes, has unquestionably diminished the danger of fire. What the London County Council has done, and what other local authorities would do well to do also, is to systematise the safeguarding of theatres by drawing up a precise code of rules and formulating their requirements for the information of theatrical architects and managers. It is true that complaints are heard, in London at least, from these gentlemen that the requirements of the Council are capricious, that there is no finality in their demands, and that costly alterations are occasionally insisted on which are not really necessary. But this only means that the last word has not yet been spoken in the art of theatre-building and that it is only by slow degrees that local authorities, whether in London or elsewhere, can arrive at a completely satisfactory definition of what is an ideally safe playhouse.

Meantime it is only right that every care should be taken to discover any additional safeguards that may be useful and it would be unreasonable to complain, as theatrical managers have been known to complain, of a progressive increase in the demands made upon them by the requirements of the local authority. Certainly no sympathy will be felt with such complaints among members of the medical profession, for with them the saving of life must ever be the first consideration. After a time no doubt experts will have arrived at a conclusion as to what points are essential to the safety of a theatre under modern conditions and how the dangers that arise from fire and panic may best be guarded against. It will then be possible for the local authorities in all our great towns to draw up a code of regulations which will secure the maximum of safety for playgoers while making no demands upon managers which reason and experience do not show to be essential. One of the points upon which the London County Council has lately insisted is the danger of overcrowding. And in this it seems to us that its action has been indisputably wise. The practice that prevails in theatres in all parts of the kingdom of allowing the gangways to be blocked with spectators is a most undesirable one, and in London, at least, the Council is determined to check it. Without speaking of the unhealthy ditions which must prevail in a playhouse thus overded—a point on which, among medical men, there can be no two opinions—the additional risk which would be caused in case of an outbreak of fire when the passages are filled with spectators would be very great. There were even certain theatres in London where seats used to be placed in the gangways when all other places were full; this dangerous practice, however, we are happy to say, is now forbidden.

But it is with the most recent regulations of the London County Council, in which it is understood that the Lord Chamberlain entirely concurs, that we are here specially concerned. Two of these deal with points which we have not yet touched upon. One rule provides that "the public may leave the theatre at the end of the performance by all the exit doors." This is of the first importance, and the rule deserves to be adopted by all the theatres in the kingdom, and, indeed, in the world. At the present day all theatres, it is to be hoped, have what are called "extra exits," but these are almost universally kept closed. In many playhouses the audience are not even allowed to use them except in case of emergency. The result of this state of things is obvious. Exits which the public are not accustomed to use escape notice in moments of panic. In some cases through long disuse it has ceased to be possible to open the doors. Instances have even been known where these "safety" exits have been actually barred up in such a way that escape by them from within would be impossible. The excuse urged for this extraordinary state of things is that a larger staff would be required if more than one exit in each part of the house were commonly used. This, however, is certainly not a sufficient reason for permitting so dangerous a practice. The rule that so-called "extra exits" should be always and at all times available to the public, that they should be fastened only in such a way that pressure from within would immediately open them, and that every evening at the close of the performance they should be thrown open for general use, is a wise one. The other new regulation is that the fireproof curtain is to be lowered at least once during every performance so as to ensure its being in proper working order. This again is a rule which will at once commend itself to the common sense of every thinking person. A mechanical contrivance such as a heavy fireproof curtain, unless it is constantly used, is very liable to get out of order. A cry of fire arises, and when the attempt to lower it is made the mechanism refuses to act, the curtain sticks, and an elaborate and costly safeguard proves valueless from lack of use. Certainly if fireproof curtains are to be fitted in theatres it is only reasonable that they should be lowered nightly. The amount of time taken by the operation would be infinitesimal and the additional security would be immense. Medical men, the aim of whose art is the relief of suffering, must welcome regulations such as these which aim at reducing, and perhaps ultimately abolishing, the terrible waste of life which has too often been associated with fire or panic in theatres.

◆

## The Horos Case.

On Dec. 20th, 1901, Frank Dutton Jackson, aged 35 years, and Laura Editha Jackson, aged 47 years, man and wife, were convicted at the Central Criminal Court and

# THE LANCET.

*LONDON: SATURDAY, JANUARY 18, 1902.*

## Small-pox in London.

SMALL-POX continues to increase in London, and already the number of cases notified has in a single week amounted to 250. Cases have occurred in each of the 29 districts, but the disease has been specially prevalent in St. Pancras, Holborn, Stepney, and Southwark, spreading in the main amongst persons occupying the poorer tenement houses and affecting the common lodging-house class and their associates. Judging by the experience of previous epidemics, it may be expected that the increase will be manifested for some weeks to come, and if we may draw conclusions from an interesting diagram in the last published annual report of the medical officer of health of the County of London which is based upon the death records of 60 years, there should be some falling off in March, with a further increase in April and May, and then, as the warmer weather sets in, a general decline. The small-pox in London is manifesting its effects in more distant parts of the country, and we hear of cases due to infection conveyed from the metropolis as far as Wales and Exeter. There does not, however, appear to be any evidence of pandemic small-pox. The returns of the Registrar-General show that up to the present time but few deaths from this disease are occurring in Paris, although it is probably to the small-pox in Paris last year that London now owes its infection. Germany seems exempt so far as its principal towns are concerned, as might be expected in a country where revaccination is general. But Austria and Italy appear from the records to be equally exempt—and these countries cannot claim that their immunity may be due to the same cause as Germany; and, again, the northern towns of Europe, with the exception of St. Petersburg, appear to be equally free. There is therefore ground for hoping that the small-pox of London, like the small-pox of Paris, may last for only a year, but it is probable that for the next few years it will continue to cause trouble to sanitary authorities. The fact pointed out in the report to which we have referred that the period which has elapsed between the epidemics of 1838 and 1871 was 33 years and that a like period since 1871 is now drawing to a close, suggests that we may have at the present time the beginnings of more widespread prevalence.

There has been much demand by anti-vaccinationists for the vaccination statistics of the patients recently admitted into the hospitals of the Metropolitan Asylums Board, as if there were some possibility that they would teach a lesson dissimilar to that which had been provided by every previous epidemic in every place The report which the Metropolitan Asylums Board received from its statistical committee on Saturday last tells the same story as that to which we are accustomed. 760 vaccinated persons had a fatality of 14 per cent., and 190 unvaccinated persons had a fatality of 50 per cent. It would have been well if the figures had included the deaths and recoveries of all those who were admitted during the year 1901 instead of the actual deaths and recoveries during that year, for the latter method has a tendency to include a disproportionate number of deaths owing to the short period during which the disease has prevailed in London. In a few weeks' time it will be possible to tell a more complete story, and we trust the tables, corrected in the sense which we have indicated, will be again published. The report gives interesting information of the incidence of the disease on public officials and other persons brought while in the performance of their duty into contact with cases of small-pox. It is in the highest degree discreditable to the London sanitary authorities that during the year no fewer than 21 persons were admitted into the hospitals who were employed on the work of disinfection, most of whom were the servants of borough councils. Not one of these persons, the report states, had been vaccinated since infancy. With a record such as this we are reminded that claims have been put forward for the borough councils to administer the vaccination law. We are bound to remark that their inability to take care of their own servants will not impress the public with a sense of their fitness for this duty. There is much need for the association of the work of vaccination with the disease-preventing authorities, and the neglect to secure the protection against small-pox of their own officials is distinctly discouraging.

The records of the Metropolitan Asylums Board provide useful material for the purposes of comparison. Between the years 1884 and 1900 inclusive 17,900 cases of small-pox were received into their hospitals and 2198 persons were employed therein. Of these 17 contracted small-pox, of whom 13 were not revaccinated until after they had joined the hospital ships, while four were workmen who escaped medical observation. During the past year not a single case of this disease has occurred among the staff of the hospitals. We sincerely trust that the publication of these figures will have the effect of influencing many to resort to revaccination. It should be understood that it is open practically to everyone to make himself absolutely insusceptible to small-pox, and it needs to be remembered that there is sufficient small-pox in London to render exposure to infection a possibility to all. A concluding paragraph in the report of the Statistical Committee is an extract from a report published in 1872; this report states that out of upwards of 14,800 cases of small-pox received into the hospitals only four well-authenticated cases were treated in which revaccination had been properly performed. The evidence of the value of revaccination afforded by the cases admitted in 1901 is not stated, and we do not doubt that it would have been if there had been any reason to re-state the case. Without the aid of the public, sanitary authorities and medical practitioners can do but little, but with ready coöperation the prevalence of small-pox could be largely reduced.

* * *

## Theatres and the Safety of the Public.

THE efforts which the London County Council has recently been making to secure the safety of the playgoing public have an interest far wider than the limits of the

Sweeting, Dr. W. W. E. Fletcher, and Dr. H. T. Bulstrode, three of the Board's medical staff, are dealing with the metropolitan area properly so-called, while other medical inspectors are paying visits to the sanitary and vaccination authorities in the outer ring. But Members of Parliament with inquiring minds also will be asking what the London County Council is doing to promote harmonious action among the several borough councils over which, in connexion with bubonic plague, it exercised a benevolent and a useful influence. The enemies of the Council—all of us have enemies—will not be slow to infer that the Council, now that there is a little unpopular fighting to be done, is loath to move, and that in the matter of small-pox prevention, which involves considerations as to vaccination, the less said or done the better. But if these be its views it may be found that other efforts will be made to bring together a meeting of the local authorities and to evolve a scheme of joint action which will deprive the Council of much of the credit which in the administration of the sanitary affairs of the metropolis it has, up to now, most deservedly gained. The Council, it must be remembered, possesses no jurisdiction as to vaccination. Under these circumstances the active intervention and assistance of the President of the Local Government Board may be desirable. There are no thinking people who wish to see the fair name of London as regards health jeopardised by the small but rampant body of anti-vaccinationists, nor will the working-classes welcome the decline of trade which will inevitably attend a serious extension of the present outbreak. The metropolitan medical officers of health are largely independent officers, able, and withal anxious, to do their duty. But in their endeavours they must be supported by the head of the public health service of the country, and we trust that Mr. Long will make it clear at an early date in the session that he intends the Vaccination Act to be enforced and all other measures against the spread of the disease to be taken; that efforts shall be made to bring about the notification of chicken-pox, that sanitary authorities shall provide expert advisers to assist in the diagnosis of small-pox, that contacts shall be sought out and watched, that school-children shall be inspected as to their vaccination, that vaccination and revaccination shall be promoted by all available means, and, finally, that the medical officers of health and the vaccination officers shall be *encouraged* and supported in their efforts

## THE LANCET RELIEF FUND.

A perusal of the annual report of the Almoners of this Fund, which will be found on page 186, serves as a reminder, if any were needed, that the falling-off in more recent years of the number of those seeking admission into the medical profession does not of necessity point to an increase in the worldly prospects of those who are already within its portals. We do not say, judging from our experience in the administration of the Fund which it has been our privilege to provide for the past 13 years, that it can be claimed that there is any widespread necessity for relief among the profession. We believe that the exact truth is rather that there are many who are just able to earn a bare living out of the exercise of that profession which cost them (or their parents) so much to enter—that the receipts and (of necessity) the outgoings are so evenly balanced that there is absolutely no margin to provide against even the least adverse circumstance which may arise. Our experience in the administration of the Fund teaches us that this is a true statement of the position in which many of our brethren find themselves day by day, week by week, and year by year, with the ever-present anxiety to make both ends meet and yet to keep up appearances—a position in itself well-nigh intolerable. Add to this the inevitable suffering of the sensitive husband and father who, having failed to make even a small provision by insurance, or by joining such an excellent body, for instance, as the Society for the Relief of Widows and Orphans of Medical Men, sees absolutely no prospect of leaving anything behind him for the future support of those dependent upon him should his professional career be cut short, and the picture we draw is on all fours with many of the cases which come before the Almoners. During the year 1901 no less than 82 applications for assistance were received—a number far in excess of those received in any previous year, which rather points to the fact that members of the profession, in common with their lay brethren, are feeling the increased cost of living brought about by the state of affairs in South Africa. Of these 82 applications 35 were dealt with by gifts of money ranging from £5 to £20, and two cases were relieved by way of loan. In addition, one applicant required the guarantee of his funeral expenses to enable him to enter a convalescent home, which the Almoners granted. The total relief afforded involved the expenditure of £383 10*s.*—the largest amount distributed in any one year since the inauguration of the Fund in 1889. Many letters from those who have benefited have been received, expressing gratitude for prompt relief which has enabled them to mitigate, and oftentimes to overcome, their difficulties. To those who have so ungrudgingly helped us in our labour of love it is again our privilege to make public acknowledgment of our indebtedness—to Sir William Selby Church, Bart., the President of the Royal College of Physicians of London; to Mr. Henry Greenway Howse, the President of the Royal College of Surgeons of England; to Sir William Turner, K.C.B., the President of the General Medical Council; to Sir Henry Pitman, for many years the Registrar of the Royal College of Physicians of London; and also to the late Sir William MacCormac, Bart., K.C.B., K.C.V.O., who during his five years of office as President of the Royal College of Surgeons of England did so much for the Fund. The application form of The Lancet Relief Fund will be found in our present issue, and can be readily detached for use in case of need. We again take an opportunity of asking those of our readers who may have occasion to assist in furthering any application made for relief from this source to note carefully the conditions on which applicants become entitled to participate in the benefits of the Fund, as it is still found that many requests are put forward which are so far outside the objects of the benefaction that they cannot be entertained, and from such applications nothing but disappointment can result. All applications should be made on the prescribed form, and should be sent to the Secretary of The Lancet Relief Fund, The Lancet Offices, 423, Strand, London, W.C.

## THE MACCLESFIELD INFIRMARY.

Like the war in South Africa, the contention between the governors and the honorary staff of the Macclesfield Infirmary has once or twice been prematurely reported to be ended. At last, however, an agreement seems to be made, for at a meeting of the governors held on Jan. 13th a motion was carried with one dissentient to the effect that in future "when a vacancy occurs it shall be advertised at least twice in the recognised medical journals, the applications for the vacancy submitted to the honorary medical staff with a requisition that they carefully consider the same and, if possible, select at least three suitable candidates from which the governors shall appoint" No great fault can be found with this resolution, except, perhaps, that the word "requisition" instead of "request" is needlessly peremptory, and that the governors must consider house surgeons as inanimate objects, as the pronoun "which," according—among other authorities—to sentenced—the former to 15 years' penal servitude and the latter to seven years'. The prisoners, commonly known as Theodore and Laura Horos, were at the head of a *quasi*-religious institution, the "Theocratic Unity and Purity League." The chief tenets of the league were set forth as chastity, celibacy, self-abnegation, and secrecy, and the induction of novices was accompanied by the most grotesque ceremony and mystic observances, such, in fact, as were calculated to lead to mental bewilderment and especially in the case of emotional subjects. A fruit and nut diet was enjoined as a means to a higher spiritual development. That the order was established for the main purpose of robbing individuals who had the misfortune to be engaged within its meshes there can be no shadow of doubt. Had the *modus operandi* of the prisoners ended here the case against them would have resolved itself into a charge of vulgar fraud. Who were the persons sought for membership of the league and what were the means by which they were to be entrapped? The majority of the victims were impressionable young women attracted by matrimonial advertisements which the male prisoner caused to be inserted in a newspaper. Frank Jackson represented himself as being the son of the female prisoner and by specious promises of marriage he succeeded in persuading the girls to leave their homes and to join the Purity League. Then by subtle devices under the guise of religious instruction he obtained control of them bodily and mentally and with the concurrence and aid of his wife he encompassed their moral ruin. The details of the procedure adopted by the prisoners are too revolting to narrate.

Before the magistrate the following charges were preferred: (1) of having obtained by fraud the moneys and goods of certain young women whom they had lured into heir power; (2) under the Criminal Law Amendment Act, of having procured these women for immoral purposes; (3) of having been guilty of rape upon the person of Daisy Adams, aged 16 years; and (4) of an unnatural offence upon another young girl. Committed for trial and indicted upon all these charges, they were proceeded against on the third charge only at the Old Bailey—not that the others were of a venial character. Although Daisy Adams—whom they had obtained from her mother, a person in sympathy with their religious tenets, under the promise to adopt her and to teach her certain subjects—had arrived at the age at which consent might be urged in defence, it was contended by the prosecution that she had been coerced and forced by the prisoners and was not therefore a willing agent. The Solicitor-General in his opening speech remarked that "the formation of the Theocratic Unity and Purity League was part of the machinery employed to attract certain emotional members of the public and eventually produce their downfall."

In addition to the statute crime for which he was indicted Frank Jackson was proved to have been guilty of practices which, in the words of the late Sir James Paget, were "a filthiness forbidden by God, an unmanliness despised by men" Beyond a direct denial on oath by both prisoners of the offences charged against them the male prisoner pleaded "the chastity of impotence," a plea negatived by the highest medical evidence. That both the man and the woman were endowed with more than ordinary intellectual acuteness and power, and notably so in the case of the woman, only served to aggravate their heinous offences, for they prostituted their intellects in the service of their depravity. Primarily their aim was to obtain money from their dupes, but they must have been steeped in vice and debauchery to practise such means as they did, not only to commit robbery but by having control over their victims, whom they viciously regarded as silenced by the knowledge of their shame, to secure themselves from retribution for their guilt. The female prisoner, because of her age and sex, received a comparatively mild sentence. Probably Mr. Justice Bigham, who tried the case, had reason for making such disparity in the punishments, but to our minds Editha Jackson's claim to indulgence was visionary. Her past history was exceptional in the variety and malignity of her crimes. She was the wife of the male prisoner, and yet she aided and abetted in the committing of the most brutal and lustful assaults on several members of her sex. Possibly his Lordship regarded her mental condition as hovering over the confines of sanity and lunacy. The case will long be remembered as one of the most remarkable ever tried in our criminal courts.

# Annotations.

"Ne quid nimis."

## THE CONTROL OF SMALL-POX IN AND AROUND THE METROPOLIS.

The progress of small-pox in London raises the important question as to whether the new metropolitan borough councils and the boards of guardians are one and all using their best endeavours to control the march of the epidemic, and whether there is about their procedure that active coöperation which can alone ensure a measure of success. As regards the borough councils an opportunity is now afforded them of justifying before a somewhat cosmopolitan audience the new dignity and pomp which the legislature has recently conferred upon them. The administrative bodies of this and other countries are observing closely the manner in which London is combating the deadliest foe which now threatens its inhabitants, but against which science has afforded a sure and certain protection. Now that Parliament has reassembled the President of the Local Government Board will doubtless be inundated with questions as to the extent of the outbreak and the precautions which are being taken against its spread. We shall watch with some curiosity the answers which will be given by Mr. Long to these queries. Fortunately, a stronger or more determined Minister has never filled the departmental post in question, and we may rely upon it, generally, that he will deal firmly with any recalcitrant sanitary or vaccination authorities. There are already indications that the anti-vaccinationists are endeavouring to curtail the useful work both of the medical officer of health and of the vaccination officer, and it is a fortunate matter that neither of these officers can be removed without the sanction of the central authority. The educated portion of the community will look to Mr. Long to defend the public health of the metropolis with vigour and he may rest assured of the cordial support of the medical profession in his endeavours. He is, we believe, already making detailed inquiries, both inside London and in the ring of unions which immediately surrounds it, as to what steps are being taken. Dr. R. D.

in fermentation in the production of alcohol we added: "It is therefore not chimerical entirely to suggest that the day may come when we may not only owe our increased facilities of locomotion to the much-abused microbe but some of our effectual means of artificial illumination also." The following statistics and facts show how nearly this idea is being realised. France, according to *Engineering*, now produces a good deal over 55,000,000 gallons of spirit annually, much of which is denatured, rendering it liable to a relatively small duty, so that it is probable that soon its price will not be more than 1*s.* 4*d* per gallon. An association exists to promote the use of spirit for industrial purposes. At the Agricultural Exhibition in Paris last year 15 spirit motors were at work and they created considerable interest. It is stated that the results obtained with these motors has been satisfactory as a whole and that they tend to prove that success will be complete with motors built specially for consuming spirit. Amongst the advantages of spirit for motive power may be mentioned the fact that spirit motors have more elasticity than have petroleum motors and work more quietly, and, moreover, as we have previously pointed out, they are free from the objectionable smell occasioned by the petroleum motor. The efficiency of the spirit motor is also said to be greater Fermentation and its microscopic agency may after all prove a formidable rival to the naphtha wells of the world, for the ferment is ubiquitous and its food is abundant everywhere, while the sources of petroleum are far from us and widely scattered.

## A UNIFORM METHOD FOR THE ESTIMATION OF ARSENIC.

In our issue of August 24th, 1901, p. 541, we announced that a joint committee of the Society of Chemical Industry and of the Society of Public Analysts had been appointed with the view of deciding the question of a standard method for the estimation of arsenic and especially of small quantities as in beer. At that time this committee had already reported that it felt in a position to prescribe a method but that before taking that step it was advisable to submit this method to a continued practical trial. This has now been done with the result that the Marsh-Berzelius method, with certain precautions, is recommended. For generating the hydrogen from zinc diluted hydrochloric acid seems preferable, but first it must be ascertained to be arsenic-free; or it can be partially distilled after first oxidising with bromine and then reducing with sulphurous acid, the first portions coming over containing the arsenic as arsenious chloride. Sulphuric acid can be purified similarly by heating it with a little pure sodium chloride. The generating-flask should be of a capacity of 200 cubic centimetres and should be provided with a 50-cubic-centimetre tapped funnel and an exit-tube, the latter being connected with a drying-tube containing, first, a roll of lead paper or cotton-wool saturated with lead solution, then a wad of ordinary cotton-wool, next a layer of granulated anhydrous calcium chloride and again a wad of cotton-wool A hard glass tube drawn out to a point 0·092 inch in diameter is connected with this drying tube. A control experiment is first made which will show whether the starting of the actual experiment is justified by the non-appearance of a mirror after 20 minutes. Standard arsenical mirrors are prepared by adding a few cubic centimetres of a solution of arsenious oxide in hydrochloric acid (each cubic centimetre containing 0·001 milligramme of the oxide). The arsenic standard solution or the suspected fluid is added after the hydrogen has been coming off for 20 minutes. The standard mirror tubes are sealed while full of hydrogen and preserved and placed upon a white card for comparison. The test is described to be of such delicacy that, using quantities of 20 grammes of a solid substance or 20 cubic centimetres of a fluid, it will give a distinct indication of one part of arsenious oxide in 7,000,000. There is little doubt that this method will be very generally adopted and a universal method is certainly desirable in order that analytical discrepancies may be avoided. While, however, this report seems to provide a satisfactory method probably for the generality of cases we do not gather whether it would answer in specific cases, as, for example, in the case of organo-compounds of arsenic, notably the cacodyls. Nor would the report appear to throw any light upon the exact combination of arsenic present, say, in beer. We may hope that the Royal Commission on Arsenic which will meet again shortly will have some definite information on this subject brought before it.

## ROYAL MEDICAL BENEVOLENT COLLEGE.

We learn with pleasure that under the will of the late Mr. J. F. France, consulting ophthalmic surgeon to Guy's Hospital, a sum of money has been placed at the disposal of the Council of Epsom College to provide pensions for aged and necessitous members of the medical profession. The election is vested in the Council of the College for the time being, following the regulation which the donor formulated in the case of the 10 female scholarships at the Royal Asylum of St. Anne's Schools which he purchased and presented to the College. Mr. France was a warm supporter of the institution from its initiation and for many years was a most regular attendant at the meetings of the Council. This second benefaction leaving the election of the pensioners in the hands of the Council emphasises the confidence felt by the testator, derived from his personal experience, in the care with which the recipients of these great boons are selected by the governing body. The Council at its last sitting determined to found pensions of £30 a year to be called the "France Pensionerships." The first election to these pensions will take place at the meeting of the Council on April 2nd.

## DYSARTHRIA AND OTHER SPEECH-SYMPTOMS PRODUCED BY A SUBCORTICAL GLIOMA.

Cases of small encapsuled tumours affecting the functions of limited areas of the brain by acting upon the subcortical nerve-tracts concerned are not of common occurrence, especially as regards the functions of speech-utterance. Dr. James Stewart of Montreal, in *American Medicine* of Dec. 21st, 1901, records a case of special interest not only as illustrating the diagnosis and successful removal of the tumour but as showing that dysarthria and not aphasia is the characteristic form of speech-disturbance met with in the case of tumours subcortical in relation to Broca's centre. Following the lead of Lichtheim and Déjerine, it has been the custom with many neurologists to call speech-disturbances attending lesions in this situation "subcortical motor aphasia." Dr. Bastian in his recent work on aphasia has clearly shown that these subcortical lesions do not give rise to aphasia but to dysarthria or anarthria. The following case illustrates the above points. The patient was a man, aged 37 years, by occupation a painter. He was healthy and free from syphilis. He first came under Dr. Stewart's observation in December, 1900, with transient attacks of total loss of speech. He had been in perfect health, with the exception of a slight frontal headache, until the preceding August, when he was suddenly seized with an attack solely characterised by total loss of speech-utterance for about 30 minutes. Six weeks later he had a precisely similar attack, and up to the time of his admission (December, 1900) he had in all 10 such seizures, the last one occurring on the morning of admission. "During the attacks he understood perfectly what was said to him and knew what he desired to the Twentieth Century Dictionary, is "now used of things only." A long discussion took place over the motion, some contending that it was taking power out of the hands of the governors. One gentleman went so far as to say that he did not intend to take any further interest in the infirmary "now that it had closed its doors to women doctors." Possibly, when the present irritation has subsided, the interests of the patients may again appeal to him. After the motion was carried the mayor announced that he was authorised by the medical staff to place before the governors the withdrawal of their resignations. It is stated that Miss Clarke intends to practise in Macclesfield, where she will doubtless be treated with courtesy by her colleagues in the profession, and where she must now be well known.

## THE METROPOLITAN WATER-SUPPLY.

THE report on the condition of the metropolitan water-supply for the month of November, 1901, has recently been published. It is a matter for regret that the publication of the Water Examiner's report should always be so long deferred, and it is not easy to understand why there should be so much delay in the matter, especially when it is remembered that the report is always printed in the same form and that much of the information given month after month is identical in substance. During the month of November the water of the Thames was in good condition at Hampton, Molesey, and Sunbury. The height of the river varied from a point three inches above to one 10 inches below the average summer level. At West Molesey the rainfall during the month amounted to only 0·45 inch. The average amount of water abstracted from the Thames daily was 118,110,369 gallons, that from the Lee 39,372,315 gallons, and the "springs and wells" owned by the companies produced a daily average amount of 48,239,786 gallons. The total daily amount, including that supplied from Hampstead and Highgate for non-domestic purposes, was 205,887,957 gallons, which represents a daily consumption per head of 32·68 gallons for a population estimated at 6,300,724 gallons. The daily amount supplied per head varied considerably in the cases of the different companies. The greatest amount supplied was that given by the Chelsea Company which was 42·21 gallons per head; the smallest amount given was that supplied by the East London Company, which was at the rate of 27·27 gallons per head. For the accuracy of these figures the companies are responsible, and it does not appear that the Water Examiner has the power, even should he have the wish, to ensure their accuracy. In regard to the approximate amount of water delivered for other than domestic purposes the Chelsea Company estimates that 20 per cent of its supply, "exclusive of waste," is so used. The East London Waterworks Company estimate, that no less than 30 per cent. of its supplies are used for non-domestic purposes. A large proportion of this water is, we believe, accurately measured. It may be noticed that the East London Company in the return which it gives of the details of its supply does not make an allowance for "waste." Neither the Kent Company nor the Grand Junction Company makes any such allowance. All the other companies mention "waste." It is by no means clear what the reader is meant to infer from this word "waste" used in this connexion. During the month of November the number of supplies given by the companies was increased by 1508, and the total number now amounts to 936,641. A constant water-service is now professedly given by four of the eight companies, the Chelsea, the East London, the Grand Junction, and the West Middlesex. The Lambeth Company professes to give constant service to only 77·4 per cent. of its customers, so that nearly a quarter of them are still suffering from the inconveniences of an intermittent supply. Dr. T. E. Thorpe, the analyst to the Local Government Board, reports that all the samples of the Kent Company's water which were examined showed that it was, as usual, of "high organic purity and excellent quality." The specimens taken of the New River Company's water were clear, but "in the cases of the other companies, in some samples minute amounts of suspended matters were present." Of the samples which were collected on Nov. 11th and 12th full analyses were made. It is of interest to compare the relative amount of organic impurity which was present in these specimens. It was as follows: "Taking the average amount of organic impurity in a given volume of the Kent Company's water during the nine years ending December, 1876, as unity, the proportional amount contained in an equal volume of water supplied by each of the metropolitan water companies was: Kent 1·1, New River 1·3, Southwark 2·5, Chelsea 2·6, East London 2·7, West Middlesex 2·8, Grand Junction 2·9, and Lambeth 3·0." It is readily seen from these figures that the water supplied by the Kent Company and by the New River Company was of very much better quality than the water supplied by the other companies, and that the analysis of that supplied by the Lambeth Company gave the least satisfactory results.

## THE DISTRIBUTION OF PLAGUE.

DURING the week ending Jan. 5th, 1902, 9 cases and 6 deaths from plague have occurred throughout Egypt; all these cases and deaths have occurred among the native population at Tantah, 5 of the deaths taking place out of hospital. Notwithstanding the many difficulties which have been encountered at Tantah, the Director-General of the Sanitary Department considers that the work is going on there as satisfactorily as possible, thanks to the energetic measures carried out by Graham Bey and the European and native staff under his direction. As regards the Mauritius a telegram from the governor received at the Colonial Office on Jan. 10th states that for the week ending Jan 9th 37 cases of plague occurred, of which 22 were fatal. As regards the Cape of Good Hope, a telegram from the governor received by the Colonial Office on Jan. 8th states that for the week ending Jan. 4th the cases of plague at the Cape Peninsula numbered 1, a European; at Port Elizabeth and all other places the cases numbered 0. The deaths from plague were as follows:—Cape Peninsula, 0; Port Elizabeth, coloured persons 1, natives, 1; all other places, 0. The area of infection remains unchanged The cases of plague in persons under naval and military control numbered 1, a private in the 2nd Dragoons, at Greenpoint Camp, Cape Town.

## THE MOTOR AND THE MICROBE.

*Apropos* of an annotation on this subject in our issue of Jan. 4th, p. 44, we learn from an interesting article in *Engineering* of Jan 10th that alcohol for driving motors is coming into gradual use in several continental countries. In France this is owing to the duty paid on all imports of mineral oil and to the enormous development in the cultivation of the beet, the production exceeding by far that necessary to meet the home consumption of sugar. "There is no exaggeration," says our contemporary, "in stating that the experiments which are being carried out extensively in France for developing the use of spirit in the production of heat, light, and power have more for their object to come to the aid of the agriculture of the country than to mark a step forward in any branch of industry." We said in the annotation referred to that "the idea of microbes as a source of motive power appears at first sight preposterous, but a little reflection will show that indirectly even for this purpose micro-organisms may be very intimately concerned." And, again, after pointing out the rôle of micro-organisms the number of sick that poured in. That seems to us to have been, in the main, both the cause and the explanation of the temporary breakdown of the hospital service which took place and about which so much has been heard.

## SMALL-POX IN LONDON.

THE small-pox returns for the last week show no diminution in the number of cases. On Saturday, Jan. 11th, 48 fresh cases were notified and removed; on Sunday, Jan. 12th, there were 30 fresh cases; on Monday, Jan. 13th, there were 53 fresh cases; on Tuesday, Jan. 14th, there were 37 fresh cases; and on Wednesday, Jan. 15th, there were 24 fresh cases.

## THE CHEAP PISTOL.

SINCE we last referred to this subject in December there have occurred a "Brighton tragedy" and an "Eastbourne tragedy," presenting the usual features of murder and suicide by shooting with a pistol, and the New Year had not been two days old before the "Hunstanton tragedy" showed again the danger of allowing deadly weapons to be bought and carried without restriction. If any member of Parliament should care to ask for a return showing the number of deaths attributable to the revolver in Great Britain during 1901 he would, we believe, find that they were fully equal to those resulting from many of the minor actions that have been fought in South Africa Parliament in this session no doubt will have plenty to occupy it to the exclusion of such matters as legislation for the restriction of the sale of fire-arms. At the same time the subject may at any moment, when it is too late to legislate, become one of considerable importance The coronation of His Majesty is approaching, and by that date London is likely to contain a large number of foreign monarchs and their representatives, while our own Royal Family will be constantly before the public. We have no intention of being pessimistic or alarmist but to shut the door after the horse is stolen is proverbially a useless exercise of caution, and the murder of the late President of the United States should serve to remind us that any miscreant with a disordered brain and 3s. 6d. in his pocket may at any time take a valuable life if he is reckless or mad enough to sacrifice his own.

## SEWAGE DISPOSAL AT CHICHESTER.

THE cathedral city of Chichester has been most unfortunate in the matter of its disposal of sewage. It was only six years ago that a complete scheme of main drainage was carried out at a cost of upwards of £42,000. Now the citizens are face to face with an expenditure of a sum which will probably not fall short of five figures for the improvement of the outfall works. This new expense has been forced upon the corporation owing to a law-suit successfully brought against the city by Lord Gifford for allowing the discharge of foul effluent from the works into the harbour. The sanction of the Local Government Board is now being sought by the corporation to borrow the necessary sum for carrying out an improved scheme at the outfall works. The corporation have adopted the Native Guano Company's system, by which it is proposed to enlarge the tanks to three times their present size, and in lieu of treating the sewage with eight grains of chemicals per gallon, as in the past, to substitute 50 grains 60 gallons per head of the population per day are to be so treated, and all that there may be in excess of this is to be received in rough filters or placed upon the land. The company's scheme provides that it shall take the whole matter of the outfall works and the disposal of the sewage entirely out of the hands of the council. This requires the fullest investigation before the corporation's seal is affixed to the contract. Sewage-disposal is a very important matter; so, also, must be to Chichester the proposal of the company to convert the sludge into manure. The question of Chichester's outfall sewage works is no new one to the Local Government Board. In the summer of 1899 cases of typhoid fever were traced directly to the consumption of sewage-contaminated cockles from the harbour, and on that occasion the assistance of the Whitehall authorities was sought.

## DYSENTERY IN ASYLUMS.

THE discussion upon dysentery in asylums which was opened by Dr. F. W. Mott, F.R.S., at the meeting of the Epidemiological Society on Dec. 13th, 1901, will be resumed to-night (Friday, Jan. 17th) at 11, Chandos-street, Cavendish-square, W., at 8 30. Many physicians associated with the work of asylums are expected to take part in the debate, and Dr. J. W. Washbourn, C.M.G., will open a discussion on "The Relation of the Dysentery of Asylums to that of South Africa," his paper being illustrated by lantern slides and specimens.

## THE EARLY HISTORY OF THE ALCOHOL QUESTION IN RUSSIA.

AT any time a trustworthy account of the "liquor traffic" in Russia would have been of interest, and at the present moment so much attention is being bestowed on the alcohol question as it affects this country that a Russian report recently issued by State Councillor J. N. de Lodijensky is worthy of note. From this report, which is the joint work of M. A. G. Pedashenko and M. A. P. Vihliaief, it appears that the Russian people have been accustomed to the use of alcoholic beverages from the earliest times. Ancient manuscripts and legends bear witness to the fact that even in prehistoric times the people were given to feasting and that "med" and beer were enjoyed by the poor whilst wine derived from grapes was drunk by the rich. The "med," like our English mead, was made from honey and is described as having been "slightly intoxicating"; of the composition of the beer we are not told. The art of distillation was introduced into Russia from Western Europe at the end of the fourteenth or at the beginning of the fifteenth century, and from that time the consumption of spirits rapidly increased. The reigning princes granted power to some of the people to sell alcoholic drinks and they also established places for its sale under their own management At a later period under John III. the Crown assumed the sole right to make alcoholic beverages. This led to illicit brewing and distilling. John IV., who is best known in England as Ivan the Terrible, established a number of public houses about the year 1555. These houses were afterwards let on lease. Under this system the sole right to keep public-houses and to sell alcoholic drinks in any given district was vested in a single individual. The right to the monopoly was sold for a term of years to the highest bidder and the fee was paid to the Crown. In some places the monopoly was retained by the Crown and the trade was carried on by persons nominated by the Government and bound on oath to trade honestly. Of the spirits used some were prepared in the public-houses; some were manufactured by merchants or landed proprietors. In the districts in which the monopoly was sold the spirits were made by the holders of the licence. In those parts of the country which were retained by the Crown the arrangements for carrying out the work were rather peculiar. Civil officers called "inn-heads" were appointed to conduct the business, and they received no payment for their work, but on the contrary they had to make good a deficit should the returns fall short of the sum fixed by the Government as the minimum. On the other utter." During the last few attacks a slight "deadness" and numbness of the right index and middle fingers were momentarily felt. Optic neuritis and headache of a severe character now developed, and later there appeared facial spasm followed by paresis of the lower facial muscles on the right side. There was also a weakness of the right half of the tongue. Articulation now became difficult, at first as regards labials and later as regards all sounds (dysarthria), and finally a condition of complete inability to utter words (anarthria) prevailed. Cerebral tumour was diagnosed, and after trephining and opening the dura mater a subcortical tumour was found in the lower part of the ascending frontal convolution. The tumour measured one inch by three-quarters of an inch; it was encapsuled and presented a firm consistency. Microscopic examination proved it to be a glioma. "On removing the tumour about two ounces of turbid watery fluid escaped from beneath it, leaving a cavity just over the first part of the horizontal branch of the fissure of Sylvius." The power of articulation began to return gradually on the eighth day after operation, and when the patient left the hospital on the twenty-eighth day articulation was nearly normal. He, however, spoke slowly, labials especially requiring deliberate effort. Handwriting, which was at first incoördinate (graphic ataxia), also began to improve and in a short time it became quite normal. Muscular power in the right hand was always retained. Dr. Stewart points out that there is no clinical difference between the speech-disturbance of subcortical lesions and bulbar lesions, and that differential diagnosis is only possible by the help of collateral symptoms. The proximity of the tumour to the cortical hand centre accounted for the incoördination of writing which existed when the tumour had nearly attained its full size.

## THE PLASTIC SURGERY OF THE FACE.

THE art of repairing or replacing lost features has a great antiquity. In India especially, where removal of the nose has been long a favourite form of punishment, attempts to shape a new nose were made centuries ago and they met with a large amount of success. In Europe Tagliacozzi of Bologna devised several methods of replacing a lost nose, and his work describing his procedures was published in 1597. Yet for nearly 200 years these methods were disused, and it was not until near the commencement of the nineteenth century that a revival occurred in this important cosmetic art. Even at the present time many surgeons still recommend artificial noses as vastly superior to anything that surgery can effect, but the present results are very remarkable The various methods of skin-grafting have done much to facilitate these operations, but the surgeon is especially aided by the thinness, elasticity, and vascularity of the skin of the face. Dr. J. B. Roberts delivered the Mütter lectures at the College of Physicians, Philadelphia, and he chose the Plastic Surgery of the Face for his subject, and these lectures, a revised edition of which he has now published, provide probably the best extant description of the various procedures which may be adopted for repairing deformities of the face. There are two main methods by which lost tissue may be replaced. In one a pedunculated flap of skin is raised from a neighbouring part and is twisted on its pedicle until it occupies the new position, where the edges and surfaces of the tissues have been prepared for it. This is the "Indian" method and is in some ways the more satisfactory as the risk of sloughing of the flap is extremely slight. The chief objection against it is that it necessitates a scar at the spot from which the flap is removed. The other method is represented by the Tagliacotian operation. In this the flap is taken, not from the face, but from elsewhere—from the patient's arm or leg—or from some other person. In this method the risk of sloughing is undoubtedly increased except when pedunculated flaps are used, but in the latter case it is necessary to fix the arm so that the flap may be applied. This constrained position is, at first at least, very wearisome. Antisepsis and asepsis have enabled surgeons to undertake very extensive plastic operations, and it is not improbable that this group of procedures is capable of wide extension.

## THE KING'S SANATORIUM.

WE desire to draw the special attention of our readers to a notice which appears in our advertisement columns relative to the Prize Essay in connexion with the King's Sanatorium. The advertisement gives the replies of the Advisory Committee to sundry questions which have been addressed to the committee by intending competitors.

## SANNA'S POST AND THE BLOEMFONTEIN WATERWORKS.

EARL ROBERTS went to Woolwich on Jan. 13th to present medals to a number of officers and men who had returned from South Africa, and especially to honour the members of the Q Battery of the Royal Horse Artillery for their memorable and gallant fight at Sanna's Post. The Commander-in-Chief was accompanied by Lieutenant-Colonel E. J. Phipps Hornby, R A., V.C., who commanded the battery on the occasion in question. There is no need to detail all that took place at Sanna's Post and the manner in which Q Battery so greatly distinguishing itself, because these facts are already well known. As the subject is connected, however, with one of the most lamentable incidents in the medical history of the war we need not apologise for referring to it. A somewhat new and strong light has been thrown upon the occurrences which took place at Sanna's Post and which led to the capture of Colonel Broadwood's force and to the ambush into which the Q Battery accidentally fell by an article in the *Standard* of Jan. 14th. According to the account of the special war correspondent of the *Standard* the very hard fighting that occurred at this post was but part and parcel of a carefully prepared scheme to capture and destroy the waterworks. "After our entry into Kroonstad, whence President Steyn fled with wonted celerity, there came into my possession," writes the correspondent, "certain of his papers. Among them were many telegrams, marked 'confidential,' from commandants in several parts of the Orange River Colony. On March 27th Chief Commandant Christian De Wet sent the following telegram to Staats President Steyn at Winburg: 'Will it not be well to destroy the waterworks at Bloemfontein and Modder River, if that has not been done already? There are many troops requiring much water, and this may, perhaps, force them to camp elsewhere.' This advice was repeated with greater urgency on the 28th, and two days later Christian de Wet was on the ridge of hills overlooking the waterworks outside Bloemfontein and the doomed bivouac of Colonel Broadwood." The natural inference to be drawn from these and other confidential telegrams is that De Wet's object was not to ambush the British forces, but to destroy the waterworks near Bloemfontein, a step which he had repeatedly urged upon the council of war. Whether the capture of these waterworks by the Boers should have been foreseen and guarded against at all costs by the British troops it is not for us to say, but no one can doubt that their loss was followed by disastrous consequences as far as the health of Lord Roberts's army was concerned A deplorable epidemic of enteric fever suddenly occurred after the capture of these waterworks by the Boers, and the hospitals with the British forces were, for the time being, quite unequal to provide for has therefore kindly reduced these to "less difficult phraseology" from which we learn that "the nerves contain or consist of colloidal solution which resembles jelly before it jells. Nerve action is simply the passage to and from conditions of gelatification and solution through electrical discharges. . ... Negative ions, termed anions, may have several negative charges. Heat promotes gelatification while cold makes solution less stable, &c." In fact, we believe that we might have understood something of the matter, which seems very similar to Du Bois Reymond's electrical theory, had it not been for that well-meant but unfortunate determination to give it to us in "less difficult phraseology." But "jells" is a sort of word which is suggestive of the late Lewis Carroll's Humpty-Dumpty.

## THE HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK.

IN aid of the above institution a performance took place at the St George's Hall, Langham-place, W., on Jan. 13th. A new and original four act play, entitled *The Scarred Hand*, was performed by a company of amateurs. The play is written by Messrs. Val de Garno and Leopold Montague, and the former name veils the identity of a medical man. No doubt, in consequence of this fact, the medical details which play a prominent part in at least one act of the play were free from the impossibilities and incongruities which are usually wont to accompany such matters behind the foot-lights. In the accident ward of "St. Paul's Hospital," for instance, when a "bad accident case" seems likely to die the nurse in charge did not, as we have seen before now on the London stage, fall upon her knees and pray for Divine aid, but with more practical, if less spiritual, instincts she promptly rang for the house surgeon This gentleman had not failed to impress upon her with regard to the case in question that "if he bleeds, he dies," and it was in consequence of this warning and the appearance of hæmorrhage, leniently screened, we may add, from a shuddering audience, that she took prompt steps towards the electric bell. The interest of the play is well developed from first to last and its incidents are not of the sensational or morbid character which the title had rather led us to anticipate. A hospital ward and dramatic conversations between a pallid "accident," who is also an ingenious burglar, and a buxom nurse cannot fail to give rather a curious and almost laughable effect when presented on the stage to an audience largely familiar with the quiet realities of hospital life. Nevertheless, the play interested, amused, and never bored. Even professed playwrights do not always achieve equally pleasing results. In the end virtue triumphs, villainy is exposed and handcuffed, and the unfortunate heroine is found, after all, not to have committed bigamy. With these pleasant factors and the matrimonial success of the senior surgeon of St. Paul's even the most exacting spectator must assuredly depart well pleased. That this was the case with the audience at St. George's Hall was evident from the hearty applause and from the calls for "author," to which the joint authors (one of whom also took a part in the play) responded. The hall was well filled and no doubt the Hospital for Epilepsy and Paralysis will gain a well-earned increment

## THE CLASSIFICATION OF NERVOUS DISEASES.

CLASSIFICATION of diseases is not only of importance to the student who is enabled thereby to perceive the natural relations and affinities prevailing, but is of practical use in helping towards a clearer insight into etiology and prognosis. In the *Revue Neurologique* of Dec. 15th, 1901, Dr. N. Chataloff of Moscow propounds a classification of nervous diseases which he regards as an improvement over the etiological classification which was published by Möbius in 1898. The main division is into diseases of nutrition in a limited sense, and anomalies of structure, hereditary or acquired. Diseases of nutrition, moreover, are subdivided into quantitative and qualitative. The whole scheme may be briefly expressed as follows. 1 Anomalies of structure of a hereditary character: these include spastic paraplegia, spinal spastic paralysis, cerebellar ataxia and Friedreich's disease, syringomyelia, Raynaud's disease, progressive muscular atrophy, amyotrophic lateral sclerosis, progressive bulbar paralysis, Huntington's chorea, paralysis agitans, Thomsen's disease, tic douloureux, nodding spasm, and some cases of epilepsy. 2 Anomalies of structure which are acquired: these include cerebral, bulbar, and spinal traumatism; neoplasms of the central nervous system; hæmorrhages, thromboses, or embolisms; intermittent claudication; traumatic neuroses and psychoses; and some forms of vertigo and neuralgia. 3 Maladies of nutrition: these are characterised by disturbances of nutrition in a limited sense and either quantitative or secondary to some form of toxæmia. The quantitative group includes neurasthenia, vertigo, cephalalgia, neuralgia, and exhaustion from overwork. The neuroses of this group have long been known as "functional," but according to Dr. Chataloff they may be regarded as due to lowered conditions of nutrition (quantitative) in the nerve-centres concerned. 4. The qualitative disturbances of nutrition, arising as a rule from some form of toxæmia, include the following: encephalitis in its various forms, hemiplegia, abscess, focal myelitis in its various forms, disseminated sclerosis, hydrocephalus, meningitis in its various forms, polyneuritis, facial hemiatrophy, the post-febrile paralyses (including Landry's paralysis), the neuropathies from alcoholic, saturnine, and arsenical poisoning, tabes dorsalis, Raynaud's disease, pellagra, hydrophobia, tetanus, eclampsia, epilepsy, myxœdema, and acromegaly, the neuroses of diabetes and of Addison's disease, and some forms of hysteria, neurasthenia, chorea, and catalepsy. The classification of nervous diseases is a matter of considerable difficulty, because the etiology of many of them is but little known, while the pathological changes during the prodromal and early stages are still less known. The classification of Dr. Chataloff into four groups may serve as the starting-point for further subdivision into smaller groups showing closer affinities than the scheme is capable of showing at present.

## DELEGATE MEETING OF THE INTERNATIONAL ASSOCIATION OF THE MEDICAL PRESS.

SOME time ago we announced that the International Congress of the Medical Press, which was to have met in Brussels last year, had been postponed.[1] It will be remembered that the staffs of the medical periodical publications of the various countries were invited to constitute national associations of the medical press. These national associations were to elect and to instruct two or three delegates who were to proceed to Brussels two or three days before the meeting of the next international congress. They were then to prepare the proposals that would be submitted to the congress. We have now received information concerning an important modification of this plan. The provisional international bureau, or committee, which has its headquarters in Paris, has come to the conclusion that it is preferable not to wait for the convocation of the international congress, but to bring the delegates together at an earlier date. As the success of the congress—indeed, the holding of the congress—depends in a great measure on the delegates being able to formulate practical proposals, these hand, in the case of a surplus the money was the property of the Crown But in such cases the collectors of the returns either received presents or "were rewarded by the Czar's gracious thanks" It was thus obviously in the interest of those who conducted the business that the trade should be a good one, and it is therefore not a matter for surprise that the number of inns increased and that drunkenness became more prevalent At length the Czar Alexis Mikhailovitch, after consultation with the heads of the Church, the nobles, and his councillors, established stringent rules for the conduct of the business The lease system was abolished in the year 1681 and only one place for the sale of liquor was permitted in each town This state of things, which would probably be considered a good one by some modern temperance reformers did not long continue to be in force, and many changes have since taken place in Russia in regard to regulations for the sale of alcoholic drinks

## ST THOMAS S HOSPITAL

THE great services rendered by the London hospitals, not only to the poor of the metropolis, but to patients from all parts of the country, have long been recognised by those who are conversant with the work of the metropolitan charities An appeal which has just been made on behalf of St Thomas's Hospital by the treasurer, Mr J G Wainwright, reminds us of this and calls attention to the great increase in the demands made on that hospital in recent years involving *a heavy addition to the expenditure without there being any* corresponding augmentation of the permanent sources of income Last year relief was given in 150,000 cases The income of the charity from its landed estate in 1880 was £39,373, and the expenditure for that year amounted to £40 979 For the year ending December, 1900, these estates yielded £42 810, but the necessary expenditure had risen to £52 011, leaving the sum of nearly £10 000 to be provided by benefactions and subscriptions The surgical cases calling for operative treatment have risen from 589 in 1880 to 2127 in 1900 We know very well that a vast amount of poverty and suffering exists in the immediate vicinity of the hospital, and we sincerely trust that Mr Wainwright s appeal may meet with a favourable reception.

## CIRCULARS ON TROPICAL DISEASE

SINCE the United States have occupied Cuba, Porto Rico and especially the Philippine Islands, the necessity of a competent knowledge among its army surgeons of tropical diseases has been constantly in evidence The *Medical Record* has urged upon the Government the need of the establishment of a school of tropical medicine, but up to the present its pleas have been of no effect However, some time ago, Colonel Charles Greenleaf, then Chief Surgeon of the United States army in the Philippines concluded that it would be in the interests of the American medical profession if the results of the investigations made by the Army Pathological Laboratory workers in the Philippines were published Accordingly, a series of medical circulars treating of diseases encountered in those islands have been from time to time issued The circulars in question are sent out under the direction of First Lieutenant Richard P Strong, U S.A , in charge of the Army Pathological Laboratory in Manila. Several numbers have already been published, but perhaps the most interesting is one on bubonic plague. This circular gives a remarkably full and lucid account of that malady, and while nothing novel with regard to its origin, spread diagnosis, or prognosis is given some of the final remarks as to treatment are worthy of note. These are "Yersin serum has been found useless here Recently, however, a small quantity was obtained from Tokyo with the use of which two out of three patients have recovered Protective inoculations are not practical for the following reasons Enormous plant necessary to produce the material, working force needed to inoculate the inhabitants opposition of the people to the inoculation, and temporary benefit derived therefrom While statistics are favourable to protective inoculation study of the epidemiological features of the disease throws considerable doubt on its value "

## THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC

AS will be seen by the report printed in another column a general meeting of the governors of this hospital was held on Jan 9th for the purpose of electing a new board of management on which will fall the duty of carrying into force the new rules which were recently adopted 10 seats had to be filled and for them 10 gentlemen were nominated by an influential section of the governors who are desirous of seeing the interests of the hospital placed in good hands Needless to say this list did not include any member of the late board, two of whom, however, offered themselves for re election The latter were nominated by one of their few remaining adherents and it was characteristic of the methods employed all through the controversy by this party that they were not content with a defeat of their candidature at the meeting but sacrificed the time and the money of this charity by demanding a ballot It is to be hoped that this will not overthrow the verdict of those governors who were sufficiently interested in the matter to present themselves at the general meeting , at the same time, there is comfort in the reflection that even if two of the discredited old board are re elected they will be powerless to oppose the determination of the new members to carry out the many reforms which are so urgently needed and which have been so bitterly opposed A bright feature of the meeting, and one which bodes well for the future, was the election to the post of President of the Earl of Dudley who may be relied upon to play a most important part in rescuing this deserving hospital from the brink of ruin

## SENSATIONAL SIMPLIFICATION

WHEN a *scientific fact, familiar enough to men whose* affair is science falls upon the ear of an average newspaper reporter the printed results are often remarkable and startling Not long ago a daily contemporary described a method of "infusing life which was nothing more or less than the process of transfusion into a vein familiar to all medical men Yet to readers of the newspaper it would seem that an epoch making discovery had been recently triumphantly achieved It is unfortunate that very often the name of a genuine scientific worker is incorporated in this manner with the most exaggerated accounts of what he would describe as simply unfinished scientific observation in the pursuit of which he is engaged, the results of which are not yet obvious and the publication of which, therefore, is entirely premature We make little doubt that Professor Loeb of Chicago, whose experiments with the eggs and larvæ of the sea urchin are well known, would thus regard the sensational reports upon his work recently appearing in daily newspapers According to the ingenious writer, Professor Loeb s experiments upon the eggs of an organism which is often hermaphrodite if not parthenogenetic—experiments which are described by the reporter as achieving the development of an unfertilised egg—entail not only an explanation of cancer, but also herald the greatest discovery of the Christian era and bring us within reach, if not of the creation at any rate of the indefinite prolongation, of existence. In another newspaper we are told that "Professor Loeb's announcement is expressed in 14 statements couched in scientific language unintelligible to the laity " The reporter s made but in which the eruption prevented any reliable observation as to cicatrices; and (3) "Unvaccinated"—i.e., cases admittedly unvaccinated, or bearing no marks of the operation, and as to which no statement was made.

The gross mortality is given as 24·28 per cent. It must, however, be borne in mind that in arriving at this figure many cases of recent admissions have been included because they have been completed by death; whereas the contemporary cases which will nearly all ultimately recover cannot be included until completed by discharge. The result being that the rate of mortality above given is undoubtedly higher than it will be when all the cases have been completed and the final rate ascertained.

he total mortality-rate per cent. of vaccinated cases was 14·21; of ıbtful cases, 65 08; and of unvaccinated cases, 50 52

t is useful to consider the statistics as grouped under age periods. der 10 there were only 12 vaccinated cases and no death; six ıbtful cases, all of whom died; and 95 unvaccinated cases, of whom died—a percentage of 54 74.

Jnder 20 there were 161 vaccinated cases, of whom three died—a centage of 1·87; 12 doubtful cases, of whom seven died—a percentage of 58·33, and 161 unvaccinated cases, of whom 79 died—a centage of 49 07.

here appears to be a distinct diminution in the protective power orded by primary vaccination after the age of 20 years. The death e rising from 9 85 in vaccinated cases between 20 and 25 years of age 28 95 in cases between 35 and 40.

*ncidence of disease on public officials and other persons brought, ile in the performance of their duties, into contact with small-pox es.*—Amongst the patients admitted during the year there were no er than 21 who were employed on disinfecting work (of whom one d), most of them being servants of borough councils. Not one of se persons had been revaccinated since infancy. There were also mitted two sanitary inspectors, two dustmen, one undertaker (who d), and one medical officer of an infirmary; and three other persons, of whom assisted in removing a small pox case from an infirmary, e scrubbed the ward from which a small-pox patient had been noved, and one made beds in the lodging-house in which cases had urred. All these persons ought to have been protected by revaccination.

Against this we draw attention to the experience of the managers at their small-pox hospitals and in the ambulance service for many years past, in both of which services revaccination is always performed on engagement.

Of 2198 persons employed at the small-pox hospitals between 1884 and 1900 inclusive, in which period 17,900 small-pox cases were received into the hospitals, only 17 persons contracted small-pox, of whom 13 were not revaccinated until after they had joined the ship and four were workmen who escaped medical observation.

During the past year a very large number of new staff have joined the ships and the Gore Farm Hospital (the exact number cannot be given at present), but not one case of small-pox has occurred. Not one of the staff of the hospital ships has ever died of small pox and not one has even suffered from the disease for the past eight years.

From the year 1881 to the end of 1901 there have been employed in the ambulance service of the Board 1282 persons. Four of these persons contracted small-pox, of whom one escaped vaccination when appointed; he died; one was unsuccessfully revaccinated on joining the service, and the operation was not repeated; she died; the two others had been revaccinated and recovered.

The facts which we have briefly set forth in this report in our opinion confirm the conclusions arrived at by the special committee appointed by the managers to collate statistics after the small-pox epidemic of 1870–1–2. That committee in their report, dated July 11th, 1872, said:—

"The necessity of revaccination, when the protective power of the primary vaccination has to a great extent passed away, cannot be too strongly urged. No greater argument to prove the efficacy of this precaution can be adduced than the fact that out of upwards of 14,800 cases received into the hospitals only four well-authenticated cases were treated in which revaccination had been properly performed, and these were light attacks. Further conclusive evidence is afforded by the fact that all the nurses and servants of the hospitals, to the number at one time of upwards of 300, who are hourly brought into the most intimate contact with the disease, who constantly breathe its atmosphere, and than whom none can be more exposed to its contagion, have, with but few exceptions, enjoyed complete immunity from its attacks. These exceptions were cases of nurses or servants whose revaccination in the pressure of the epidemic was overlooked and who speedily took the disease; and one case was that of a nurse who, having had small-pox previously, was not revaccinated and took the disease a second time."

(Signed) V. B. KENNETT BARRINGTON, Chairman.

## APPENDIX.

TABLE GIVING PARTICULARS OF 1017 CASES OF SMALL-POX TREATED IN THE MANAGERS' HOSPITALS TO RECOVERY OR DEATH DURING THE YEAR 1901, THEIR CONDITION IN RELATION TO VACCINATION, AND THE MORTALITY PER CENT.

| Ages. | Vaccinated | | | Doubtful. | | | Unvaccinated. | | | Total cases and deaths. | | | Ages. |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Cases | Deaths | Mortality per cent. | Cases | Deaths | Mortality per cent. | Cases. | Deaths | Mortality per cent. | Cases. | Deaths. | Mortality per cent. | |

## NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

A SPECIAL general meeting of governors and members of the National Hospital for the Paralysed and Epileptic (Albany Memorial) was held at the hospital, Queen square, Bloomsbury, on Jan. 9th. The Earl of Dudley was elected President after he had been voted into the chair for that meeting.

Mr. H. L. **BISCHOFFSHEIM** proposed the following list of names to be elected members of the board of management: Mr. Ernest De La Rue, Mr. Melvill Green, Mr. Frederick Orridge Macmillan, Sir Alexander Mackenzie, Sir John Rahere Paget, Mr. John Danvers Power, Mr. Arnold Royle, Mr. Edgar Speyer, Rev. Prebendary Henry Wace, D.D., and Mr. James Wigan.

Dr. **GRIFFITHS** seconded.

Mr. H. H. **NELSON** said they were there that day to do what was best in the interests of the charity they had instituted, and he thought that the step proposed of turning away the old board of management and having nothing more to do with them was a very great mistake. Was it wise in the interests of the institution to eliminate from the management the whole of the members of the lay board? He proposed, therefore, that to that board should be added two members of the late board, Mr. John Pearman and Mr. F. C. Capel.

Mr. C. A. **CAMPBELL** seconded.

Mr. F. **NETTLEFOLD** spoke in favour of Mr. Nelson's views. He considered that the hospital might lose the support of a large section of subscribers who might not like this apparently off-hand way of dealing with the old governors. After all, though they had made mistakes they had been the first to acknowledge the mistakes they had made. Some consideration was due to the old board, and especially when it was borne in mind the influence which their names exerted over a large number of the subscribers.

The question was raised whether the meeting was held under the delegates cannot set to work too soon. An opportunity for such a meeting has occurred, and the provisional bureau advises that it should be utilised. The Prince of Monaco, who has distinguished himself in the field of scientific research, takes the greatest interest in the scientific press and has offered every facility and extensive hospitality to those who are striving to establish an International Association of the Medical Press. This invitation has been accepted and the delegates of the various national associations of the medical press are now called upon to meet at Monte Carlo on April 3rd next. It is important that the British medical press should take immediate action to be worthily represented. The two main points to be discussed are the protection of literary property and the statutes of the International Association of the Medical Press. If something like an agreement can be arrived at on these points, then it will be possible to convoke a large international congress to confirm or to amend the proposals made and to take action for the purpose of bringing about the practical application of the principles which will then have been widely endorsed. The first step, therefore, is to elect at the earliest possible date the British representatives. When this has been done these delegates will receive from the provisional bureau the agenda of the forthcoming meeting and other details. They will then be able to submit these documents to their respective associations and to receive instructions as to the course which they must follow on April 3rd when they meet the representatives of the other nationalities.

## THE EFFECTUAL PRESERVATION OF EGGS.

ON no subject, perhaps, is there a greater conflict of opinion than on the preservation of eggs. Some urge that the newly-laid egg should be kept dry and others that it should be kept moist or even immersed in a fluid. Of course, by effectually sealing the pores of a shell as with wax or grease the moment the egg is laid no difference in weight by the loss of moisture can occur, and it is unlikely that anything can enter the egg from the outside. There is little doubt that the change from a fresh to a stale condition is partly a question of the loss of moisture and partly a disturbance of equilibrium by external agencies. The simple method described by Sir W. T. Gairdner in our columns about a year ago would appear to establish this view. The method consists merely in greasing the eggs the moment they are laid and before they have cooled. This procedure is so successful that eggs so treated are said to be as fresh to the taste when weeks and even months old as they are when eaten an hour after being laid. It is also suggested to immerse eggs in a strong solution of silicate of soda or water-glass. In this case the preservative effect is probably due to the formation of a hard glassy silicate of lime within the substance of the shell, forming, so to speak, a perfectly airtight envelope of glass. The egg is in a way hermetically sealed. This, however, is no argument in favour of wet storage, and even by the silicating process we imagine that the absolutely newly-laid warm egg must be selected for the purpose. It is well known, further, that water-glass possesses a powerful antiseptic action. Eggs treated in this way are said to preserve their fresh milky taste for six months and to be indistinguishable from the egg taken straight from the nest. Eggs, of course, merely submerged in water would probably get stale more quickly than when kept under dry conditions. The question of the effectual preservation of eggs is of the utmost importance and one which British producers have persistently ignored, an inexplicable attitude by which much valuable food is wasted and a source of profit thrown away.

# Pharmacological Notes.

### IPECACUANHA IN PNEUMONIA.

WITH the object of depleting the lung, and as a consequence so modifying its tissues that microbic infection is counteracted, Perreau has introduced the following method of treating pneumonia.[1] One gramme of powdered ipecacuanha root is mixed with 100 grammes of mucilage and a measured tablespoonful of the mixture is given every hour for about eight hours. A certain amount of practice is necessary in order to avoid either vomiting or diarrhœa by carefully lengthening the intervals between the doses. The method is said to give satisfactory results, especially if employed early in the course of the disease.

### THE NITRO-PROPIOL TEST FOR SUGAR IN URINE.

Dr. Carstairs Douglas,[2] in an address before the Glasgow Medico-Chirurgical Society, recently discussed the value of the nitro-propiol test for sugar in urine, basing his conclusions on 200 observations. The test was fully described in THE LANCET of Feb. 17th, 1900, and a note also appeared upon its clinical application in THE LANCET of April 6th, 1901, p. 1028. Dr. Douglas concludes from his experiments that reducing agents other than sugar, which are from time to time found in urine, affect nitro-propiol in the same way as they affect the copper tests. As glucose is the most active reducing agent met with in urine its presence is frequently assumed when the reagent employed undergoes a prompt reduction. This assumption is not warranted unless the reduction is very marked and abundant. When absolute certainty is required in the case of quantities of sugar too small to act with the yeast test, the phenyl-hydrazine test is by far the most trustworthy for clinical purposes. However, when a copious and speedy formation of indigo-blue takes place on boiling diluted urine with nitro-propiol it is almost always the case that the reduction is due to sugar. The chief advantages of the nitro-propiol test are: (1) the striking and distinctive character of the reaction when positive; (2) the delicacy of the test exceeds that of Fehling's solution or the yeast test, though not phenyl-hydrazine; and (3) but little urine is required.

## VACCINATION AND THE METROPOLITAN ASYLUMS BOARD.

THE following report was presented at the meeting of the Board held on Saturday, Jan. 11th:—

### REPORT OF THE STATISTICAL COMMITTEE.

10th January, 1902.

*Statistics concerning completed cases of small-pox treated in the Board's hospitals during the year 1901.*—Instead of waiting until the issue some months hence of our usual annual report on the statistics obtainable from the whole of the Board's various institutions we take the earliest opportunity of submitting this special report upon the statistics concerning small pox in the metropolis during the year 1901. In doing this we believe we are meeting the wishes of the managers and the public. It must be understood that this document is in the nature of an interim report, and is not in substitution for the later and fuller one.

*Small-pox in London, 1901.*—Small-pox may be said to have been practically absent from London in the first five months of the year. It is true that towards the end of January five cases were admitted into the Board's hospitals, and one in the middle of February; but during March, April, and up to May 29th not a single case occurred. On the last-mentioned date a patient was admitted from Islington, on June 10th one from Whitechapel, on the 29th one from Hackney, and on the 28th and 29th one on each day from Wandsworth. During the month of July and up to August 21st single cases occurred in various parts of London. From August 22nd and onwards, however, the disease appears to have obtained a hold in the parishes of St. Marylebone and St. Pancras. Subsequently cases occurred in every one of the 31 Poor-law parishes and unions comprising the Metropolitan Asylum District.

*Vaccination.*—We have found it impossible so soon after the close of the year to prepare the usual elaborate tables of vaccination statistics. We have therefore prepared the table annexed hereto (Appendix), dealing only with cases completed—that is, died or recovered—during the year.

The cases have been divided into three classes—namely, (1) "Vaccinated"—i.e., cases having visible cicatrices; (2) "Doubtful," which includes (a) cases stated to have been vaccinated, but bearing no visible evidence thereof; and (b) cases in which no statement was

# THE LANCET RELIEF FUND.

***Almoners.***

THIS Fund, which came into operation on the 1st of February, 1889, has for its Almoners the President of the Royal College of Physicians of London (Sir WILLIAM SELBY CHURCH, Bart., M.D. Oxon, F.R.C.P. Lond.), the President of the Royal College of Surgeons of England (Mr. HENRY GREENWAY HOWSE, M.B., F.R.C.S. Eng.), the President of the General Medical Council (Sir WILLIAM TURNER, K.C.B., M.B. Lond., F.R.C.S. Eng. and Edin., F.R.S.), Mr. THOMAS WAKLEY, F.R.C.S. Eng., and Mr. THOMAS WAKLEY, jun., L.R.C.P. Lond., with Sir HENRY PITMAN, M.D. Cantab., F.R.C.P. Lond., as Honorary Auditor.

***Scope of the Fund.***

FOR the guidance of those seeking assistance and of those desirous of recommending deserving cases, it may be useful to record that THE LANCET Relief Fund is sustained solely by the Proprietors of THE LANCET, who provide every January the sum of at least £300, which is administered free of cost, with the object of affording immediate pecuniary assistance to registered medical practitioners, or to their widows and orphans, in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require. In the case of widows and orphans, in order to come within the scope of the Fund, the death of the Husband or Father must have been of recent occurrence.

***Chronic Cases ineligible.***

WHEN the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established, and, as a result, the majority of the earlier applications, being cases of *chronic* distress, and not coming, therefore, under the designation of *emergency*, could not be entertained. As the Almoners still receive applications for assistance for cases which are obviously of a *chronic* character, it is thought advisable to append a statement concerning cases of this nature which appeared in THE LANCET of Feb. 16th, 1889:—

> "We are requested by the Almoners to state that, from the character of a number of the applications received, both personally and by letter, for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood; and if relief had been afforded in the cases of those who suffer from chronic distress the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established, which is to afford prompt aid to registered medical practitioners, or to the widows or orphans of members of the profession, who, in consequence of the supervention of some unexpected emergency, which is not likely to recur, have pressing need of immediate and temporary pecuniary relief"—

And who, it may be again pointed out, are likely to be permanently benefited thereby.

## *THIRTEENTH ANNUAL REPORT of the ALMONERS*

*For the year ending December 31, 1901.*

IN presenting their Thirteenth Annual Report, the Almoners have to record that the balance in hand on Dec. 31st, 1900, was £352 17*s.* 4*d.*, to which, on Jan. 1st, 1901, the Proprietors of THE LANCET added the sum of £300, making a total sum of £652 17*s.* 4*d.* available for grants during the year 1901.

The number of applications for assistance received by the Almoners during the year was 82, of which 21 were so obviously outside the scope of the Fund that they were rejected by the Secretary by virtue of the discretionary power conferred upon him by the Almoners at their meeting on Jan. 1st, 1890; 4 were rejected by the Almoners after due consideration; in 14 cases Forms were sent but failed to be returned—probably the applicants recognised that their cases were outside the scope of the Fund; 1 applicant returned the Form but failed to comply with the rules as to the necessary testimonials; 1 applicant had been misinformed as to the nature of the Fund, and "preferred to try to battle with my present troubles rather than expose my poverty" by seeking the required testimonials; 3 applications remained uncompleted at the end of the year; 35 applicants were relieved by gifts of money ranging from £5 to £20; 2 applicants were granted loans; and 1 applicant was relieved by a guarantee of his funeral expenses, which enabled him to enter a convalescent home. The relief of the 37 cases, a detailed list of which is given in the accompanying Statement of Accounts, involved the expenditure of the sum of £383 10*s.*—the largest amount granted in any one year since the inauguration of the Fund in 1889.

The most gratifying feature in the administration of the Fund is the letters received by the Almoners from those whom they have helped, expressing their gratitude for the prompt relief which has enabled them to mitigate, and in not a few cases to overcome, their difficulties. In this connexion it may not be uninteresting to record the fact that on several occasions the Almoners have been able to consider cases and to grant relief on the actual day on which the application was received.

With reference to the gradually decreasing number of loans advanced from the Fund—in the year under review there were but two—the Almoners desire to point out that they are becoming more and more averse to affording assistance by this means, as their experience is that in but very few cases are loans ever repaid. The Almoners do not offer any explanation why there should be this neglect on the part of borrowers to fulfil their obligations: they are content to record the fact, and to act in the future on the principle of *Experientia docet.*

It is as unavoidable, perhaps, as it certainly is very regrettable, that in the administration of such a Fund as new rules and whether *ex-officio* governors could vote. The solicitor to the hospital, Mr. G. H. Bower, said that in his opinion *ex officio* governors were not entitled to vote because the meeting was under the old rules. This would exclude the medical staff from voting.

Lord DUDLEY said that he would put the question to the sense of the meeting. It did not seem to him primarily a matter of the direct interpretation of any definite rule, it was rather a matter of realisation of the general position and a common sense interpretation of the spirit of the rules. It was absurd to hold a meeting under a new constitution and to govern its proceedings by rules which related to a previous constitution. The regrettable differences between the old board of management and the members of the medical staff had ended in a decision given by the governors that the medical staff must be represented in the management of the hospital, and the medical staff were therefore made *ex officio* governors for that purpose. It was absolutely nonsensical to give them a vote with one hand and with the other to take away the new franchise for two years. He personally considered that it was a matter of common sense, and whether or not they chose to haggle and argue over the interpretation of any particular words in a transitional rule the only reasonable thing to do was to adopt what had been laid down in the report of Sir Edward Fry's committee, and as far as possible decline to raise the old issue. They should all strive to let the commencement of that year be the commencement of a new and happier era in the history of that hospital

Mr J. D. POWER said that the clear intention of the rules was that the staff should be *ex-officio* governors and should be allowed to vote immediately. There could not be a shadow of an atom of doubt on the subject, otherwise the rules which were worded in plain English did not mean what they said.

Mr. JOHN PEARMAN proceeded to remark that if certain governors were entitled to vote they had not received notices of the meeting. He was met with loud cries of "Why not?" It would, he explained, take weeks to discover who they were. This remark was greeted with interruptions, but he was allowed to go on with his speech by saying to the meeting, "*Pray do not cry out against me if I am making a* mis statement. I am only making a statement which I am informed is correct"

Mr. WALFORD said he did not consider there was any governor there who was so foolish as to be really anxious to quibble over the rules. There was no practical question before the meeting and he asked the Chairman to put the matter to the vote.

Lord DUDLEY then put it to the meeting whether *ex officio* governors should vote, and this was agreed to by 20 against 6

The meeting then proceeded to vote for the names submitted for the new board of management and the figures were as follows · Mr. Ernest de la Rue, 33; Mr. Melvill Green, 32; Mr. Frederick Orridge Macmillan, 32; Sir Alexander Mackenzie, 31; Sir John Rahere Paget, 28; Mr John Danvers Power, 31; Mr. Arnold Royle, 28; Mr. Edgar Speyer, 28; Rev. Prebendary Henry Wace, 34; Mr. James Wigan, 30; Mr. F. C. Capel, 17; Mr. J Pearman, 16

Lord DUDLEY declared all but the last two duly elected, whereupon Mr NELSON demanded a *ballot*.

Lord DUDLEY fixed Jan 23rd as the day on which the votes should be counted and the result of the ballot declared

The proceedings then terminated with a hearty vote of thanks to Lord Dudley for taking the chair

# THE LORD MAYOR'S APPEAL FOR GUY'S HOSPITAL.

THE Lord Mayor (Alderman Sir J. Dimsdale, M.P.) presided over a meeting held at the Mansion House on Jan. 15th for the purpose of supporting the appeal for funds which is now being made for Guy's Hospital. The meeting was an exceptionally large one and the proceedings throughout were marked with great enthusiasm. The most important part of them was, perhaps, the announcement of the total sum of money contributed towards the £180,000 required for the renovation and building fund, and much satisfaction was expressed when it was found that no less than £64,000 had been subscribed.

The LORD MAYOR opened the meeting by a speech in which he gave some historical facts concerning Guy's Hospital. He said that the rich and the well-to-do were quite as much assisted as the suffering poor by reason of the teaching carried on in the medical schools and the results of the untiring labours of the hospital physicians and surgeons. The results of the education given in the schools and wards were not confined to the hospital alone or to the great metropolis alone, but were at the disposal of the community at large and benefited not only this kingdom but the empire. It was a regrettable fact that owing to the want of funds wards were still closed and could not be re-opened until the benevolent public gave the wherewithal to keep them in active use Since the year 1880 agricultural depression had caused a depreciation in the income of the hospital amounting to nearly 50 per cent. The financial statement of the affairs could be put in a nutshell. To carry on the hospital efficiently and well and to make it worthy of being one of the great hospitals of London it was necessary to have an income of £60,000 a year. The only reliable income was £35,000 a year, and £25,000 a year were required in addition for the proper carrying out of the work of the institution after it had been repaired and renovated so as to make it abreast of the times. It was certain that unless its wards were healthy and sanitary the hospital had better not exist. £180,000 were wanted to bring the hospital up to date; the fabric itself wanted renovating, the wards and the adjuncts of the wards required reorganisation; and the theatres, the medical college, and the nurses' home, all required money. They must have as well a first-rate laundry and proper sanitary arrangements. The Lord Mayor then gave in detail the work that was done by the hospital.

Mr. COSMO BONSOR, the treasurer of the hospital, said that to open 150 closed beds under modern conditions of medical science and professional nursing required a heavy expenditure The sum of money necessary to build a nurses' home for 230 sisters and nurses was large, but the governors had been encouraged to do this by the generosity of the late Mr. H. Raphael who called upon Mr. Bonsor one very cold morning in the winter and, after having seen the attics in which the nurses were lodged and noted the crowded condition of their sleeping accommodation, gave a cheque for £20,000 for a nurses' home.

The following motion was proposed by Mr. LEOPOLD DE ROTHSCHILD, seconded by the Hon. ALBAN GIBBS, M.P., supported by Mr. A. C. COLE and Mr. R. K. CAUSTON, M.P., and carried unanimously:—

> That this meeting having heard the speech of the Right Hon. the Lord Mayor and the statement of the treasurer showing the present urgent financial needs of Guy's Hospital, earnestly commends the same to the support of the citizens of London and to the benevolent public throughout the country, in the hope that sufficient assistance may be immediately rendered to enable the governors to maintain the work of that great institution in a state of completeness and efficiency.

Dr. FREDERICK TAYLOR, senior physician of the hospital, in moving a vote of thanks to the Lord Mayor thanked him for affording the opportunity of making that appeal at the Mansion House.

Mr. H. G. HOWSE, President of the Royal College of Surgeons of England and senior surgeon to the hospital, in seconding the motion for the vote of thanks, drew attention to the enormous change that had taken place in surgery in the last 30 years, requiring surgeons to spend a large part of their time in operating theatres.

Mr. COSMO BONSOR declared the vote of thanks to be passed with acclamation, and after a short reply from the LORD MAYOR the proceedings ended.

CREDITON SICK NURSING ASSOCIATION.—The annual meeting of the promoters of this association was held at the Masonic Hall, Crediton, on Jan. 9th, when Lady Audrey Buller, president of the association, occupied the chair. The report of the association stated that the work during 1901 had pursued its usual even course. The financial report was satisfactory, the subscriptions and donations amounting to £103 16s 10*d*., and the receipts from paying patients to £16 5s 6*d* The nurse's statement of work showed that 327 cases had been attended during the year and the nurse had paid 4416 visits Of these patients 66 had recovered, 30 had been relieved, three had been removed to the workhouse, 17 had died, one had been removed to a convalescent home, and 15 were still on the books. Of the £10 granted for relief £8 18*s*. had been expended. The financial statement showed the total receipts to be £127 17*s*. 10*d*. and the expenditure to amount to £100 18s., leaving a balance in hand of £26 19*s*. 10*d* The endowment fund stood at £197 5*s*. 10*d*., against £222 5s. 10*d* in the previous year, £25 having been transferred to the maternity fund.

SEAMEN'S HOSPITAL SOCIETY.—At a quarterly general court of the governors of the Seamen's Hospital Society held at the Institute of Chartered Accountants, Moorgate-place, E.C., on Jan 10th, it was stated that the work of the society had been progressing satisfactorily and that 25,249 patients had been treated in the various hospitals and dispensaries of the society during the past 12 months. 72 students had entered the School of Tropical Medicine during the past year. The committee of management regretted to state that the society's income had fallen short of the expenditure *during the past 12 months, so much* so that the offer of a convalescent home had been refused, as the committee had not felt that they could undertake the liability of its maintenance

# VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 75 of the largest English towns 9422 births and 5183 deaths were registered during the week ending Jan. 11th. The annual rate of mortality in these towns, which had been 20·1 per 1000 in the preceding week, declined last week to 18·3 per 1000. In London the death-rate was 18·6 per 1000, while it averaged 18·1 in the 74 other large towns. The lowest death-rates in these towns were 5·5 in Hornsey, 9·3 in Wallasey, 9 5 in East Ham, 10 3 in Kings Norton, 10·7 in Northampton, 10·8 in Walthamstow, 11·0 in Smethwick, 11 6 in Barrow-in-Furness, and 12 2 in Handsworth; the highest rates were 22 6 in Reading, 23·3 in Rotherham, 23·6 in Bootle, 25·2 in Preston, 26·3 in Rhondda, and 28 8 in Wigan. The 5183 deaths in these towns included 482 which were referred to the principal zymotic diseases, against 510 in the preceding week; of these 482 deaths 124 resulted from measles, 82 from diphtheria, 78 from whooping-cough, 58 from scarlet fever, 53 from small-pox, 45 from "fever" (principally enteric), and 42 from diarrhœa In Hornsey, Norwich, Rochdale, Huddersfield, and in nine other smaller towns, no death was recorded during the week from any of these diseases; in the other towns they caused the highest death-rates in Norwich, Birmingham, Aston Manor, Grimsby, Salford, Preston, Rotherham, York, and Middlesbrough. The greatest proportional mortality from measles occurred in Great Yarmouth, Aston Manor, Grimsby, Preston, Sheffield, Rotherham, York, and South Shields; from scarlet fever in Wolverhampton, St. Helens, and Middlesbrough; from diphtheria in Hanley and Cardiff; from whooping-cough in East Ham and Rhondda; from "fever" in Smethwick and Birkenhead; and from diarrhœa in Wolverhampton and Bury. Small-pox caused 45 deaths in London, four in West Ham, two in East Ham, one in Croydon, and one in Willesden, but not one in any other of the 75 large towns. There were 872 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, Jan. 11th, against 506, 538, and 666 at the end of the three preceding weeks; 305 new cases were admitted during the week, against 161, 226, and 261 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 3033 and 3137 on the two preceding Saturdays, had further declined to 2864 at the end of last week; 250 new cases were admitted during the week, against 247, 263, and 313 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 393, 425, and 452 in the three preceding weeks, declined again last week to 361, and were 284 below the corrected average number. The causes of 73, or 1 4 per cent., of the deaths in the 75 towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Portsmouth, Bristol, Norwich, Leicester, Nottingham, Bolton, Salford, and in 39 other smaller towns; the largest proportions of uncertified deaths were registered in St. Helens and Northampton.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21 5, 22 6, and 23 2 per 1000 in the three preceding weeks, declined again to 19 6 during the week ending Jan 11th, but exceeded by 1 3 the mean rate during the same period in the 75 large English towns. The rates in the eight Scotch towns ranged from 10·9 in Perth and 16 0 in Paisley to 20 5 in Glasgow and 21·0 in Greenock. The 633 deaths in these towns included 23 which were referred to measles, 19 to diarrhœa, five to whooping-cough, four to diphtheria, three to "fever," and two to scarlet fever. In all 56 deaths resulted from these principal zymotic diseases last week, against 86 and 70 in the two preceding weeks. These 56 deaths were equal to an annual rate of 1·7 per 1000, which was also the mean rate last week from the same diseases in the 75 large English towns. The fatal cases of measles, which had been 36 and 30 in the two preceding weeks, further declined again last week to 23, of which 19 occurred in Glasgow and four in Dundee. The deaths from diarrhœa, which had been 23 and 12 in the two preceding weeks, rose again to 19 last week, and included 11 in Glasgow, three in Aberdeen, and two in Paisley. The fatal cases of whooping-cough, which had been seven and 12 in the two preceding weeks, declined again last week to five, of which two were registered in Glasgow and two in Edinburgh. The two deaths from scarlet fever were both recorded in Greenock and two of the three fatal cases of "fever" in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 188, 166, and 182 in the three preceding weeks, declined again last week to 142, but exceeded by 19 the number in the corresponding period of last year. The causes of 28, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·9, 26·8, and 29·4 per 1000 in the three preceding weeks, declined again to 25·0 per 1000 during the week ending Jan. 11th. During the past four weeks the death-rate has averaged 26·8 per 1000, the rates during the same period being 19 6 in London and 20 9 in Edinburgh. The 182 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 32 from the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 15, 10 and nine in the three preceding weeks; of these three resulted from diphtheria, three from "fever," two from whooping-cough, one from measles, and one from diarrhœa. These 10 deaths were equal to an annual rate of 1·4 per 1000, the zymotic death-rate during the same period being 1·9 in London and 0 6 in Edinburgh. The fatal cases of diphtheria, which had been three, two, and three in the three preceding weeks, were again three last week. The deaths referred to different forms of "fever," which had been four, five, and two in the three preceding weeks, rose again last week to three. The mortality from whooping-cough exceeded that recorded in the preceding week; while that from diarrhœa showed a decline. The 182 deaths in Dublin last week included 23 of children under one year of age and 57 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons were slightly less numerous than in the preceding week. Five inquest cases and six deaths from violence were registered; and 79, or more than one-third, of the deaths occurred in public institutions. The causes of 20, or more than 10 per cent., of the deaths in Dublin last week were not certified.

### VITAL STATISTICS OF LONDON DURING DECEMBER, 1901.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the cities and boroughs in the county of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 10·6 per 1000 of the population, estimated at 4,543,757 in the middle of last year. In the three preceding months the rates had been 12·4, 13·8, and 11 6 per 1000 respectively. The rates were considerably below the average in Kensington, City of Westminster, St Marylebone, Shoreditch, Lambeth, and Woolwich; while they showed the largest excess in St. Pancras, Holborn, Bethnal Green, Southwark, and Camberwell. During the four weeks ending Dec. 28th, 656 cases of small-pox were notified in London, against 157, 347. and 413 in the three preceding months; of these cases 99 belonged to Holborn, 84 to Stepney, 73 to St. Pancras, 48 to Southwark, 41 to Battersea, 32 to Poplar, and 30 to Finsbury. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 163, 284, and 427 at the end of the three preceding months, had further risen to 666 on Dec. 28th; the weekly admissions averaged 173, against 44, 72, and 110, in the three preceding months. The prevalence of scarlet fever showed a considerable decline from that recorded in any recent month; among the various metropolitan boroughs this disease was proportionally most prevalent in Stoke Newington, Finsbury, Bermondsey, Camberwell, Deptford, and Greenwich. The Metropolitan Asylums hospitals contained 3080 scarlet fever patients on Dec. 28th, against 3096, 3281, and 3186 at the end of the three preceding months; the weekly admissions averaged 297, against 288, 412, 939, and 352 in the three preceding this—the very essence of the object of which is *prompt* relief in urgent cases—there should be a loophole for the fraudulent obtaining of its assistance. To give that immediate relief so necessary in the majority of cases, the Almoners must necessarily rely largely upon the statements made by the applicants and upon the covering testimonials required from medical men and from clergymen or ministers of religion in the districts in which the applicants reside. Two instances of fraud—both committed by the same person—have, the Almoners regret to say, been brought to their knowledge during the past year, in which grants were obtained in the year 1900 by means of false statements and of forged testimonials. It is difficult to devise a means of wholly defeating such infamous conduct without subjecting worthy applicants for assistance to unnecessary delay and possibly painful inquiry into the causes of their distress; but every practicable effort will continue to be made to safeguard the funds at the disposal of the Almoners.

Mr. Henry Greenway Howse, F.R.C.S. Eng., having succeeded the late Sir William Mac Cormac as President of the Royal College of Surgeons of England in July last, thereupon became an Almoner of the Fund. The present Almoners desire to record their appreciation of the late Sir William Mac Cormac's services to the Fund for five years and the excellent advice which he was ever ready to give

| *Balance at Bank, Dec. 31, 1901* ... | | | | | 269 | 7 | 4 |
| | | | | | £652 | 17 | 4 |

I find by the Bankers' Book that the actual Balance on Jan 1st, 1901, to the credit of the Fund was £352 17*s* 4*d*., to which the sum of £300 was added by the Proprietors of THE LANCET on Jan. 1st, 1901

The balance at the Bank on Dec. 31st, 1901, was the sum of £269 7*s* 4*d* I have also checked the receipts for disbursements and find the above account strictly accurate

January 6th, 1902. HENRY A. PITMAN, Hon Auditor.

months. Diphtheria was also less prevalent during December than it had been in either of the two preceding months; the greatest proportional prevalence of this disease occurred in Fulham, St. Pancras, Hackney, Bethnal Green, and Camberwell. There were 1369 diphtheria patients under treatment at the end of last month, against 1499, 1570, and 1504 at the end of the three preceding months; the weekly admissions averaged 160, against 248, 243, and 200 in the three preceding months. The prevalence of enteric fever showed some diminution as compared with that in recent months; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in Chelsea, Stoke Newington, Hackney, Holborn, Bethnal Green, Bermondsey, and Camberwell. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 292, 291, and 245 at the end of the three preceding months, had further declined to 195 on Dec. 28th; the weekly admissions averaged 21, against 50, 38, and 32 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Holborn, Bethnal Poplar, Southwark, and Camberwell. The 18 cases of puerperal fever included three in Islington, and two each in St. Pancras, Poplar, Camberwell, and Lewisham.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending Dec. 28th the deaths of 6558 persons belonging to London were registered, equal to an annual rate of 18·8 per 1000, against 15·4, 15·4, and 20·0 per 1000 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 11·4 in Hampstead, 13·7 in Stoke Newington, 15·0 in Wandsworth, 15·5 in Paddington, 16·0 in Woolwich, and 16·2 in Lewisham; the highest rates were 22·7 in Bermondsey, 23·4 in Finsbury, 24·2 in Bethnal Green, 24·4 in Hammersmith, 24·7 in Holborn, and 25·2 in Shoreditch. The 6558 deaths from all causes during the month included 655 which were referred to the principal zymotic diseases; of these 90 resulted from small-pox, 244 from measles, 52 from scarlet fever, 128 from diphtheria, 63 from whooping-cough, 28 from enteric fever, and 50 from diarrhœa. The lowest death-rates from these diseases were recorded in Chelsea, St. Marylebone, Hampstead, Stoke Newington, and Woolwich, and the highest rates in Kensington, Hammersmith, Islington, Holborn, Shoreditch, and Bethnal Green. The fatal cases of small-pox, which had been 24, 29, and 73 in the three preceding months, further rose last month to 90, of which 12 belonged to Holborn, 11 to Hammersmith, 11 to Stepney, seven to St. Pancras, six to Southwark, and five to Bermondsey. The 244 deaths from measles showed a slight increase over the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Kensington, Hammersmith, City of Westminster, Islington, Shoreditch, and Bethnal Green. The 52 fatal cases of scarlet fever were considerably less than the corrected average number; the greatest proportional fatality from this disease occurred in Kensington, St. Pancras, Bethnal Green, Southwark, and Bermondsey. The 128 deaths from diphtheria were 83 below the average number in the last four weeks of the 10 preceding years; the metropolitan boroughs in which the greatest proportional mortality from this disease was recorded were Fulham, St Pancras, Finsbury, Bethnal Green, and Deptford. The 63 fatal cases of whooping-cough showed a decline of more than 100 from the corrected average number; this disease was proportionally most fatal in Stepney, Poplar, Lambeth, Camberwell, and Lewisham. The 28 deaths referred to enteric fever were 111 less than the average number in the corresponding periods of the 10 preceding years; the highest "fever" death-rates last week were recorded in City of Westminster, Islington, Holborn, and Battersea. The 50 fatal cases of diarrhœa were slightly below the corrected average number; among the various metropolitan boroughs the greatest proportional fatality from this disease occurred in Hammersmith, Fulham, St. Marylebone, Hampstead, Shoreditch, and Poplar. In conclusion, it may be stated that the aggregate mortality in London from these diseases during December was more than 18·8 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths among children under one year of age to registered births, was equal to 173 per 1000. The lowest rates of infant mortality were recorded in St. Marylebone, Hampstead, Hackney, Holborn, Southwark, and Camberwell; and the highest rates in Hammersmith, Chelsea, Finsbury, City of London, Shoreditch, Bethnal Green, and Bermondsey.

# THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: W. S. Lightfoot to the *Eagle;* E. H. Saunders to the *Vivid* for Keyham Naval Barracks; J. Dudley to the *Lion;* and A. Patterson to the *Vivid* for Devonport Dockyard. Staff Surgeons: J. Barry to Haslar Hospital, temporary; J. Jenkins to the *Andromache;* R. Miller to the *Liffey;* and A. MacLean to the *Collingwood.* Surgeons: G. T. Bishop to Haslar Hospital; G. M. O. Richards to the *Irresistible;* A. H. Prichard to the *Redbreast;* and J. S. Dudding to the *Antelope.*

### ROYAL ARMY MEDICAL CORPS.

Colonel J. H Moore, retires on retired pay on account ill-health.

### VOLUNTEER CORPS.

*Royal Engineers:* 2nd Gloucester (the Bristol): Surgeon-Lieutenant T. Carwardine resigns his commission. *Rifle:* 2nd Volunteer Battalion the Northumberland Fusiliers: Surgeon-Lieutenant D. K. Muir to be Surgeon-Captain. 2nd (Hertfordshire) Volunteer Battalion the Bedfordshire Regiment: The undermentioned officer resigns his commission, with permission to retain his rank and to wear the uniform of the battalion on retirement: Surgeon-Captain R. L. Batterbury. 3rd Volunteer Battalion the South Wales Borderers: John William Davies is re-appointed Surgeon-Captain. 3rd (the Blythswood) Volunteer Battalion the Highland Light Infantry: Surgeon-Lieutenant J. W. Logie to be Surgeon-Captain.

### SOUTH AFRICAN WAR NOTES.

Civil Surgeon Reid who was reported to be severely wounded at Tweefontein was Godfrey Forrest Reid, M.A., M.D., B.Ch. Dub., late district surgeon at Bethlehem, Orange River Colony, South Africa. He died on Dec. 27th, 1901.

The following have been discharged from hospital to duty: Major D. R. Hamilton, R.A.M.C., Captain C. B. Martin, R.A.M.C., and Lieutenant W. J. P. Adye-Curran, R.A.M.C. Major D. R. Hamilton is returning home from South Africa in the *Kildonan Castle.*

### AFFAIRS IN SOUTH AFRICA.

As regards our military progress and the general aspect of affairs in South Africa the reports from that country are on the whole satisfactory. Among the many other unexpected things which have occurred in the course of this war no one appears to have foreseen that while Mr. Kruger was safely taking his opulent ease in Europe his *confrère,* Mr. Steyn, would be still found in the field, and that many of the hardest and most obstinate of our foes as well as some of the most redoubtable leaders of the Boers should have come from his part of the country and not from the Transvaal; but so it is. It was only to be expected that with the present season there should be an increase of enteric fever among our troops serving in South Africa, and a glance at the sick returns which have been recently published suffices to show that such has been the case. There is, unhappily, a good deal of this fever at the present time and the causes of it must be indeed widely spread, for it would seem that wherever there are British troops cases of enteric fever are almost sure to occur. Both in this country and in the colonies there exists naturally enough a good deal of indignation at the accusations of all kinds that have appeared in the continental press—of Germany in particular—against our officers and men in South Africa. We need not say that they are utterly unfounded and are so base and absurd, indeed, that it is surprising they should ever have been published, or if published, credited, by intelligent and decent people.

### THE PRINCIPAL MEDICAL OFFICER IN INDIA.

Colonel Sir Thomas Gallwey, K.C.M.G., C.B., R.A.M.C., who is selected for appointment as Principal Medical Officer in India with the rank of Surgeon-General, is

* Including membranous croup.

of Gloucester, the honorary secretary of the Jenner Society, she will get every information. The society does a most valuable work and is worthy of every support —Ed. L.

*To the Editors of* The Lancet.

Sirs,—Referring to the excellent annotation in your issue of Jan 11th (p. 104) on the Relation of the Church to Sanitary Reform may I say that for the last 25 years in the administration of the cup at Holy Communion I and my colleagues have invariably used a small linen cloth to cleanse the lip of the cup after each communicant has participated? There are more reasons than one for so doing, and I have received the thanks of many for observing a precaution which unfortunately is not universally adopted. And at the communion of the sick I always request the sick person, who, of course, communicates last, to finish what little wine remains in the cup, and this is in strict accordance with the sixth rubric at the end of the Office for the Administration of Holy Communion.

My experience extends to some thousands of communicants per year, and, so far as I can trace, not one instance of mischief has resulted from the passing on of the sacred cup with the simple precaution above named.

I am, Sirs, yours faithfully,

Jan. 11th, 1902. Vicar.

## CANCER IN INDIA AND IN CHINA.

*To the Editors of* The Lancet.

Sirs,—As a correspondence on this subject is going on in your columns, it has occurred to me that your readers might like to hear the results of inquiries made by me in this direction.

In the absence of statistical reports as to the prevalence of cancer and other diseases in India, all estimates hitherto made must be regarded as tentative and conjectural. The great extent of the country and the teeming millions of its population, make it very difficult even for those who have been long resident there in a professional capacity to arrive at correct conclusions. The few hospitals in India draw their patients from immense multitudes and vast areas, so that although many cases of cancer may be constantly under treatment, the proportionate prevalence of the disease in the general population, may be much less than the medical officers of these institutions are apt to believe. It is, however, certain that neither the rice-eating Hindoos nor the flesh-eating Mahomedans are exempt. Nearly all those who have specially studied this subject believe that cancer is comparatively rare in India—much rarer, for instance, than in England. This was Walshe's opinion, and he supported it by reference to the annual report of the Bengal Medical College (1844–45), which showed that of 4080 male patients under treatment there, during a period of three years, only three were affected with cancer; and of 701 female patients, only two were cancerous, the uterus being the organ affected in both cases.

Among recent authors Davidson is of the same opinion and in support he mentions the fact that of 2657 operations at the Afzulgung Hospital at Hyderabad in 1886 only two were for cancer, while in Bombay only one per 1000 of the total deaths were due to it.

On the other hand, McLeod states[1] that malignant tumours are common among the natives of Bengal, both in hospital and private practice; in females the breast is the part chiefly affected, and in males the cutaneous system, oral cavity, and especially the penis. Hendley's experience at the Jeypore Hospital accords with this, for during the period 1880–88—when the hospital was under his charge—102 major operations were undertaken for the treatment of malignant disease. As further information seemed desirable I wrote to Surgeon-Lieutenant-Colonel Lawrie of Hyderabad calling his attention to the foregoing statement. He kindly replied as follows: "My experience of cancer is that it is as frequent in India as in England, and I have formed this opinion from observations in Calcutta, Lahore, and Hyderabad. The Afzulgung Hospital was under my charge in 1886, and that year was no exception to the rule. The small number of operations for cancer shows nothing, except that the people are averse to operation for most diseases other than stone and cataract."

With regard to the prevalence of malignant tumours in the vast North-Western Provinces and the Punjab I am indebted to Mr. Freyer for the following information. He writes: "The general impression on my mind, after 17 years of active surgical work among the poor and rich of this part of India, is that tumours of all kinds—including cancer and sarcoma—are extremely common. Epithelioma of the tongue and penis and scirrhus of the breast are particularly common." Four-fifths of the inhabitants of these provinces are Hindoos who, with few exceptions, in accordance with the precepts of their religion, never eat meat. The other fifth—being Mahomedans—may eat meat, but they are practically vegetarians, as they can seldom afford the luxury of animal food. Among these people stone also is very common.

In Kashmir, Orissa, Madras, Anam, and Cochin cancer is said to be more prevalent than in adjacent communities. The report of the Kashmir Mission Hospital for 1898, by Dr. Neve, shows that 195 operations for tumours were done in the course of the year, 70 for cancer (including 11 of the female breast), and 16 for sarcoma (including a very large one of the lower jaw and another of the abdominal wall).

Nearly all the older writers on the geographical distribution of cancer agree in stating that cancer is more prevalent in China than in any other Asiatic country. Desiring to obtain recent information on this subject I wrote to Mr. Cantlie who was then Government surgeon at Hong-Kong. He very obligingly replied as follows: "I do not think I have been without a case of malignant disease under my care ever since I came to China six years ago." Of 3608 consecutive Chinese hospital in-patients under his care 114 had cancer, or 3·1 per cent. This proportion is almost identical with that met with in large London general hospitals, like St. Bartholomew's, where I have ascertained that 3·5 per cent. of the in-patients have cancer. Of Mr. Cantlie's 114 Chinese cancer patients the primary seats of the disease were as follows: female breast, 38; upper jaw, 25; lower jaw, 14; penis, 9; uterus, 8; parotid, 5; hip, 5; tongue, 4; lip, 3; and thigh, 3. At Dr. Kerr's hospital in Canton during the year 1887 30 cases of malignant tumours were operated on, including 11 amputations of the female breast. Strange to relate Mr. Cantlie has never met with cancer of the stomach among the Chinese. With regard to their diet he says: "All Chinamen eat fish and pork at morning and evening meals. Fowls and ducks are always on the table of all but the most humble of the coolie class, and they do not have them because they cannot afford them. I hope this will be a sufficient answer to those who maintain that Chinamen live on rice. It is not nearly so true as that the Scotch live on porridge." Dr. Elizabeth Reifsnyder of Shanghai (1895) says that cancer of the uterus and female breast is very common in that part of China, where ovarian cystomata are also often met with.

I am, Sirs, yours faithfully,

Clifton, Bristol, Jan. 10th, 1902. W. Roger Williams.

*To the Editors of* The Lancet.

Sirs,—In The Lancet of Dec. 21st, 1901, p. 1763, your readers are told by Lieutenant-Colonel J. Maitland, I.M.S., that "Mr. C. B. Keetley, writing upon the subject of cancer, states that he had been informed by Dr. C. N. Saldanha that 'Hindoos suffer comparatively little from cancer.' Upon this statement of the comparative immunity of Hindoos from cancer both Dr. Saldanha and Mr. Keetley base certain arguments regarding the prophylaxis of the disease." Now, my hypotheses as to *carcinoma* were published in The Lancet of August 31st (p. 584), the abstract of Dr. Saldanha's letter not until Oct. 5th (p 939), and my comment on this letter was simply that my hypotheses "seemed to receive a certain small measure of support from some of the facts stated—e g., the freedom of the Hindoos from cancer and their carefulness to cleanse their skins." I no more made myself responsible for Dr. Saldanha's statements than I am going to for Lieutenant-Colonel Maitland's; and my hypothesis is no more based on them than Somerset House is based on Waterloo Bridge. Again, in The Lancet of Jan. 4th Captain C. Donovan, I.M.S., intervened, writing that "it was a pity Mr. Keetley did not refer to the annual reports of the medical institutions of India, obtainable at three or four accredited booksellers in London, before accepting the *ipse dixits* of Dr. Saldanha." I am much obliged to Captain Donovan for telling me about these reports and these booksellers, and should be more now in his forty-ninth year. He will pass over the heads of a number of officers of his rank; but in the present list of surgeon-generals there are many who are not far from retirement for age. Surgeon-General W. S. M. Price, A.M.S., now acting as Principal Medical Officer in India, has seen his fifty-eighth birthday, and was disqualified for the Indian Government, it is understood, because he had less than three years to serve before retirement by age.

MEDICAL AID FOR SOLDIERS ON FURLOUGH.

Soldiers on furlough who require medical aid and who are unable by reason of distance from a military station to apply for it to the officer commanding, may in future obtain the services of a civil medical practitioner, to whom they are to show their furlough paper, and the medical man will be allowed to claim from the War Office for attendance, medicines, and the like at the rate laid down in the Royal Warrant.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At a quarterly meeting of the directors of the Naval Medical Supplemental Fund held on Jan. 14th, Sir J N. Dick, K.C.B, being in the chair, the sum of £75 was distributed among the several applicants.

# Correspondence.

"Audi alteram partem."

## SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

*To the Editors of* THE LANCET.

SIRS,—In the autumn of 1900 you were good enough to allow me to call the attention of the younger metropolitan members of the profession to the advantages offered by the above society. The result was that last year we enrolled 35 new members. May I venture again to trespass on your kindness in order to point out that any qualified medical man residing within 20 miles of Charing-cross can be proposed as a member, the annual subscription being two guineas, payable for 25 years? But any annual subscriber may become a life-member within 10 years of his election by making up his subscription to 25 guineas if he shall have been under 30 years of age, to 30 guineas if he shall have been under 40 years of age, and to 35 guineas if he shall have been over 40 years of age at the time of his election as a member of the society. For the especial benefit of young members I may point out that a member under 30 years of age at the time of his election can compound for a single payment of 20 guineas, under 40 for 25 guineas, and over 40 for 30 guineas, thereby *becoming a life-member* and his widow at *once being eligible* for a grant should her circumstances unfortunately justify it. The secretary is Mr J B Blackett, 11, Chandos-street, Cavendish-square, London, W.

I am, Sirs, yours faithfully,
CHRISTOPHER HEATH, President.
Jan. 13th, 1902.

## AN UNUSUAL COMPLICATION OF INFLUENZA.

*To the Editors of* THE LANCET.

SIRS,—Although it is an ungrateful task to call in question the accuracy of a brother practitioner's diagnosis, particularly in a case which one has not himself seen and examined, yet I venture to ask Mr. J. G. Carruthers whether the case reported by him under the above heading in THE LANCET of Jan 11th, page 89, may not bear another interpretation. Certainly the diagnosis of influenza does not carry with it conviction to my mind. Surely "typical influenza" would not progress "in the usual manner" from Nov. 11th to Dec. 1st. It is, of course, a matter for regret that no post-mortem examination was made But from the clinical side alone the case reads very like one of typhoid fever terminating fatally in the fourth week by intestinal hæmorrhage Perhaps Mr. Carruthers will kindly furnish your readers with the details of the case, *particularly in regard to the behaviour* of the temperature, in order that, in accordance with his request, they may be in a better position to offer an explanation of the complication which he describes

I am, Sirs, yours faithfully,
JOHN W. MOORE.
Dublin, Jan. 11th, 1902

## THE RELATION OF THE CHURCH TO SANITARY REFORM.

*To the Editors of* THE LANCET.

SIRS,—Most of the remarks in the leading article entitled, "The Church and Sanitary Reform," in THE LANCET of Jan. 11th (p. 104), are very timely and will be welcome to the clergy who (like myself) set a high value on the close alliance which has subsisted since the time of Jesus Christ and His apostles between spiritual teaching and physical healing. I fear that the structural defects of our churches from the sanitary standpoint are almost beyond our reach as *clergy, for architects are proverbially self-opinionated*; but I doubt whether places of public assembly are one-hundredth part so dangerous as the badly-ventilated rooms where people habitually dwell. Our churches, even when crowded on Sundays, are tolerably full of fresh air most of the week, and after a large experience of public halls I can safely say that the air is purer there than in most dwellings. Had you instanced the ventilation of our elementary day-schools there would have been better support for your arguments. Most of them at 4 P.M. are scandalously oppressive.

With regard to the last part of your article I do not think that the rubric alluded to contemplates the question of infection at all. The only rubric that does so is the last one in the office for communicating the sick; in which you will see there is special provision for excusing friends and neighbours from participation Clergy who officiate at private no less than at public celebrations are expected reverently to consume all that remains of the consecrated elements, and therefore the Church accepts (for the ministry at any rate) whatever risks there may be. Life assurance societies are agreed that they are very few. This problem would become a negligible quantity if ministers who hand the chalice to communicants would wipe the edge with a fair linen cloth as they pass from one to another. The subsequent treatment of such "purificators" is very well understood Anglicans consider withholding the chalice from the *laity to* be an evasion of the words, "Drink ye all of this"; and there is a suggestion of fellowship and affection in the mutual use of one vessel for many communicants which we should be loth to lose.

I am, Sirs, yours faithfully,
C. ARTHUR LANE.
St. Mark's Lodge, New Barnet, Herts, Jan. 13th, 1902.

*To the Editors of* THE LANCET.

SIRS,—With reference to the annotation on "The Relation of the Church to Sanitary Reform," in THE LANCET of Jan. 4th, p 104, there is much truth, no doubt, in what is said therein, though it is to be questioned whether in these days of independent thought and action the influence of the clergyman is not over-estimated. I am writing, however, to express a much-felt want in connexion with the vaccination question—viz., that of good serviceable "literature" in the form of pamphlets, circulars, and bright, telling tracts suitable for distribution, reading at mothers' meetings, and for posting the clergy and others up in the incontestible facts and figures which are necessary to convince the obdurate *Even we clergymen's wives* might do something for the cause amongst the women if we had such. The subject of vaccination was recently put down for debate at a working-man's club in this parish, but the leader lamented to me beforehand that he had no statistics on which to rely, only a general sense that vaccination was wise and desirable. We are frequently inundated with pamphlets from the anti-vaccinationists, anti-vivisectionists, non-flesh-eating, and kindred faddists, but of the sort mentioned above none come our way. Is it not time, with the probability of the near spread of small-pox, that this should be remedied? I am *emboldened to add name and* address in the hope that one of your readers may either send us some such literature or enlighten us as to where it may be obtained.

I am, Sirs, yours faithfully,
ELLEN HOWELL.
*All Saints' Vicarage, Derby, Jan 14th, 1902.*

⁂ If our correspondent will write to Dr. Francis T. Bond should afford such facilities to the poorer classes, but to allow the well-to-do to escape a just toll must react eventually injuriously on one and all. Precisely as cheap medical and surgical institutions are unsound in principle and harmful to the majority, so also are cheap pathological institutes. I think gratitude is owed to Mr. White for bringing forward this important question once more.

I am, Sirs, yours faithfully,

Plymouth, Jan. 11th, 1902. F. BUSHNELL.

## FIRST AID FOR PRIMARY HÆMORRHAGE: THE WRONG TEACHING GIVEN TO AMBULANCE CLASSES.

*To the Editors of* THE LANCET.

SIRS,—"The notions stated to have been acquired at ambulance classes" are certainly startling if the holders of first-aid certificates "have got the idea fixed in their minds that they must always apply some sort of an improvised tourniquet to the limb above the bleeding part," and this treatment to include "cases of ruptured varicose veins, *superficial lacerated wounds, and compound fractures.*" It is still more startling to be told that these "notions" are in accordance with what "they had been taught to do." I do not suppose that I have either more or less common sense than any of the other honorary surgeons of the St. John Ambulance Association, but for my own part I strongly repudiate such absurd teaching as Mr. Walter G. Spencer lays to the charge of ambulance teachers. I quite agree with him as to the great danger of the tourniquet in the hands of ambulance pupils. Will Mr. Spencer kindly state what the comrades ought to have done in the following case which I extract from the *Daily Mail* of Jan. 7th? "Wm. Hickman had both his legs cut off in a chaff-cutting machine which he was working yesterday at Messrs. Whittome and Co.'s, Islington. He died before he could be taken to hospital." I am, Sirs, yours faithfully,

Ongar, Essex, Jan. 8th, 1902. J. B. G. GIDLEY-MOORE.

*To the Editors of* THE LANCET.

SIRS,—Permit me to endorse the opinions of my co-lecturers and examiners of the St. John Ambulance Association whose letters on first aid in primary hæmorrhage appeared in THE LANCET of Jan. 11th, p. 117. The first-aid treatment of hæmorrhage is most clearly and soundly laid down in the text-book of the association, and I submit that no one can take exception to that instruction, which I find, after a considerable experience as an examiner, is most strongly emphasised by the lecturers. *It is not always easy to instil* these principles into the minds of some of our pupils, but such ones seldom succeed in gaining the certificate. Moreover, many of the pupils fail to see the necessity of attending more than one course of lectures and hence forget the knowledge they have gained. But these facts do not detract from the correctness of the instruction which is given to the classes.

Your correspondent Mr. Fenoulhet is right in suggesting that a somewhat more prolonged course of instruction would be beneficial, but in a great number of classes this plan is carried out by lecturers, much to the advantage of the pupils. I am quite sure that when intelligently carried out first aid has been often the means of bringing to the doors of medical men "living" patients instead of "dead" people.

I am, Sirs, yours faithfully,

Streatham, S.W., Jan. 13th, 1902. M. COATES.

*To the Editors of* THE LANCET.

SIRS,—Permit me through your columns to express my thanks to Mr. Walter G. Spencer for his admirable letter upon this subject. I am sorry to say that I have taught the errors alluded to until this winter, but having seen many cases on a par with those so fully stated by him I had no difficulty in convincing myself that the present teaching was as erroneous as it was injurious and for the first time decided not to teach a class except in my own way. Here arose difficulties which I could not brush aside. If I taught my own views my pupils would not pass the necessary examination, and their chances of gaining the valuable cups, &c., given for competition would be *nil*, and to teach as formerly was out of the question. In this dilemma I wrote to the secretary of the Fife Colliery Surgeons' Association asking permission to express my views on the subject at its next meeting on Nov. 23rd, 1901. He replied that he was pleased to hear of my intentions, but unfortunately this letter was followed by another on Dec. 3rd in which it is stated that my "remarks could be received only informally, the main object of the association hitherto being for the ethical side of our profession."

After such a snub I need scarcely add that my paper was not read, that my class is still unopened, and my pupils as anxious as ever. My views and cases run parallel with those mentioned by Mr. Spencer, and with very slight modifications I agree with his treatment. Now, Sirs, What am I to do? I trust that Mr. Spencer's letter will be more successful in arousing the profession *generally* to take an interest in this matter which I failed to obtain *locally*—and that someone will reply to my query—What am I to do?

I am, Sirs, yours faithfully,

JOHN MACDONALD, L.R.C.P. Edin.

Lochgelly, Fife, N.B., Jan. 15th, 1902.

## THE SANATORIUM TREATMENT OF CONSUMPTION.

*To the Editors of* THE LANCET.

SIRS,—It would be wise to pause and to consider whether the money now being provided for sanatoriums to *cure* consumption could not be more advantageously spent to *prevent* the same by producing over large areas the hygienic conditions under which tuberculous diseases slowly and surely die out. Dr. Lubbock of Norwich, who taught an out-door active life, open windows in dormitories, beef-steaks and porter, has done much good for those who have condescended to learn of a *provincial* Englishman.

I am, Sirs, yours faithfully,

Framlingham. GEO. E. JEAFFRESON.

## REVACCINATION.

*To the Editors of* THE LANCET.

SIRS,—In view of the present epidemic of small-pox in London it would be highly instructive as well as interesting to know what percentage of persons attacked by the disease had been *successfully revaccinated*, and whether cases have occurred of persons who had recently (say, within six months) been revaccinated contracting the disease. Perhaps some of your correspondents who are on the medical staff of the small-pox hospitals would kindly afford me this information.

*I am, Sirs, yours faithfully,*

Jan. 8th, 1902. J. BRANDER, L.R.C.P. & L.R.C.S. Edin.

## SUSCEPTIBILITY TO REVACCINATION.

*To the Editors of* THE LANCET

SIRS,—While thoroughly agreeing with Dr. F. W. Andrewes that the publication of statistics by various practitioners would be of use to the cause of vaccination, I fear that there *will be great discrepancies owing to* the various methods of vaccination employed, and this will be well instanced by a comparison of the results obtained by Dr. Andrewes and by myself. Curiously enough he has vaccinated at St. Bartholomew's Hospital 171 persons, and in the midst of a large number of vaccinations recently performed by me I have a batch of 193 revaccinations performed at one place—namely, the office of the Ocean Accident Corporation in Moorgate-street, E.C.; of these 162 were males and 31 were female clerks or officials on the staff. Out of the whole number of revaccinations there was not one single failure, all the arms developing well-marked vesicles in the three places scarified. Among these cases six had been recently vaccinated with negative result, but in my hands they showed no insusceptibility. In 140 cases the vesicles were large and well formed, being 72·53 per cent.; in 31 cases the vesicles were moderate in size, being 16·06 per cent.; and in 22 cases the vesicles were small but not under a quarter of an inch in diameter, being *just under 11·4 per cent.*

With regard to these results I think it right to say that the only lymph used was that of the Jenner Institute, obtained through Messrs. Allen and Hanbury, and the method of vaccinating was as follows: The arms were first washed with obliged if he had added the address of one of the accredited persons.

I will now deal with Lieutenant-Colonel Maitland and Captain Donovan exactly on the same principles as those which I applied in dealing with Dr. Saldanha, and Captain Donovan will find the process quite different from a mere acceptance of *ipse dixits*. Lieutenant-Colonel Maitland says that in Madras "cancer is very prevalent amongst Hindoos." Captain Donovan says that "Colonel Maitland speaks for the Madras General Hospital where cases from all over the Madras Presidency come for operation." Lieutenant-Colonel Maitland I myself may add, occupies the high position of senior surgeon to that hospital and professor of surgery in the university. The population of the Madras Presidency *is 40,000,000 and that of the city 500,000*, of whom nearly four-fifths are Hindoos. What does Lieutenant-Colonel Maitland write when he comes to figures? He says: "In the wards of the Madras General Hospital cases of cancer affecting Hindoos are *almost* always to be found. At the time that I write I have *three* Hindoos in my wards suffering from the disease" The italics are mine, "*almost* always." "*Three.*" And they come from among 40,000,000 of people, 30,000,000 of whom are Hindoos!

No one has said that the Hindoos *never* suffer from cancer. What I said in my paper of August 31st was that they rarely suffered from cancer of the *stomach*. Neither Lieutenant-Colonel Maitland nor Captain Donovan mention the stomach, although they refer to cancer of "the penis, the jaws, throat, cervix uteri, and breasts, &c." Unless the reference is somewhere concealed in this "&c." I am at a loss to know what bearing Captain Donovan's letter really has on the substance of my paper, or why he should plunge into the discussion at all, especially in a manner so reckless that, even in correct*ing the form "Hindoo,"* his reproof falls as heavily on Colonel Maitland and on the dictionaries as on me. He goes on to say, "Of course, the word 'Hindoos' is employed by Mr. Keetley in a very loose sense and might have passed muster 50 years ago as of sufficient scientific accuracy, but in this more enlightened twentieth century," &c., in the same style. The term "Hindoos" is employed by me as referring to Hindoos only. It is not used by me at all except in reference to Dr. Saldanha's letter. In my original paper I asked gentlemen for facts bearing on my hypothesis, and particularly requested (1) that the distinction between carcinoma and sarcoma should be carefully observed, and (2) for exact references to published sources of information. In spite of this "enlightened twentieth century" and its "scientific accuracy," neither Captain Donovan nor any of the other gentlemen who have responded has paid the slightest attention to these reasonable requests. Each flings his general impressions at my head as if they were half-bricks. But each gentleman, whether gentle or otherwise, remains responsible for his own statements so long as I refer to him when referring to them.

Perhaps some Indian medical officer will kindly tell me whether the Mahomedans circumcise or not. I have asked a number of well-informed and travelled people this question in vain. Of the four parts to which Lieutenant-Colonel Maitland refers as "very common" seats of cancer in Madras two are the penis and the uterus. He also says that cancer is much more common among Hindoos than among Mahomedans. Now, in THE LANCET of Dec. 1st (p. 1764), Dr. H. R. Andrews, quoted by Dr. James Braithwaite, says that "the Jews are much less subject to cancer than we are and that they are especially free from cancer of the uterus." Dr. Braithwaite says that this is because the Jews take so little salt, but on that point Mr M. Bernstein contradicts him absolutely in the same page (p. 1764). There is one, and perhaps only one, point of difference between Jews and most Christians on which we shall all agree—viz., that the Jews have less foreskin and therefore less accumulation of smegma præputialis than persons with foreskins. Now the first part of my hypothesis, as given on August 31st, is that the "specific cause" of carcinoma "flourishes in either the secretions or the cells of the skin-glands, including the mammary gland—e.g., milk, butter, cheese, *sebaceous material, and sweat*"; smegma præputialis I specially mention in THE LANCET of Oct 5th (p. 939). The bearing of this on the occurrence of cancer of the uterus is obvious. Its bearing on the frequency of cancer elsewhere is also clear, though less obvious, and it is important, because if carcinoma is in any way a contagious disease any increase or decrease of cancer in a situation like the penis or the uterus, where it is attended by discharge, is an increase or decrease of foci of infection, and therefore leads to increased or decreased general frequency of the disease.

There are other ways, I acknowledge, in which circumcision may diminish the frequency of carcinoma—viz., by lessening liability to syphilis and gonorrhœa and to other causes of chronic ulcerations which may lead the way to carcinoma.

Lastly, may I wish success to your efforts to obtain the appointment of a commission to inquire into the causes of cancer? I am, Sirs, yours faithfully,

Grosvenor-street, W., Jan. 10th, 1902. C. B. KEETLEY.

---

## VOLKMANN'S CONTRACTURE.

*To the Editors of* THE LANCET.

SIRS,—A point of great importance has been omitted from my paper on Volkmann's Contracture owing to a mistake of mine during the correction of the proof-sheets. It is to the effect that Professor Oppenheim of Berlin refers briefly to ischæmic paralysis in his "Text-book of Nervous Diseases," 1900. Here he emphasises the importance of *normal* electrical reactions as the most characteristic feature in the diagnosis of this deformity.

I am, Sirs, yours faithfully,

Jan. 11th, 1902. LEONARD S. DUDGEON.

*To the Editors of* THE LANCET.

SIRS,—I have read Mr. Leonard S. Dudgeon's paper on "Volkmann's Contracture" in THE LANCET of Jan. 11th, p. 78, with great interest. "Volkmann's contracture" appears to me to be so much better a way of naming the deformity than "ischæmic paralysis"; it commits us to no theory as *to causation. There is one slight error in the paper which* I hope I may be pardoned for correcting. Mr. Dudgeon says, "Tendon lengthening first advised by Mr. Page has since been carried out by Mr. Littlewood, Mr. Barnard, and others, &c." If Mr. Dudgeon will again refer to the cases he has quoted he will see that I performed the operation on Dec. 5th, 1898, and that Mr. Page performed his operation on Dec. 20th, 1898, 15 days later. Since performing the two operations referred to I have operated on a third case, with a very satisfactory result, the inclosed short notes of which I shall be glad if you will insert. A female child, aged three years, was admitted under my care into the Leeds Infirmary on August 12th, 1900. She was suffering from the typical deformity—Volkmann's contracture. This had appeared after a fracture of the lower end of the right humerus in May, 1900. The fracture was treated with an anterior rectangular splint, which was kept on for five days; on being removed a large sore was found on the anterior surface of the forearm, near the elbow-joint. At the time of the operation there was a large scar in this position and the contracture was extreme. The operation was performed on August 28th, 1900. All the tendons were lengthened on the front of the forearm. It was a difficult operation, as the tendons were such slender structures. In this case I lengthened them so that I could put up the fingers in the slightly hyper-extended position. The patient made a good recovery. I saw her yesterday (Jan. 12th, 1902). She has now quite an excellent hand, with full use in it.

I am, Sirs, yours faithfully,

Leeds, Jan. 13th, 1902. H. LITTLEWOOD.

---

## THE LIVERPOOL PATHOLOGICAL DIAGNOSIS SOCIETY.

*To the Editors of* THE LANCET.

SIRS,—As clinical pathology is in its infancy and will claim an increasing number of workers the question as to the fees of the above society and of pathologists generally should be now considered by a representative committee. I trust Mr. C Powell White will initiate such action. *I think* no one will seriously deny that the work is worthy of consulting fees. Such is the opinion of most London hospital medical staffs. There can only remain the broader question whether medical services are adequately rewarded when compared, say, with the legal profession or trade. The comparison is unfavourable, more especially when we consider the value of our work to the community. It would be to the interests of both the profession and the public to consider fully whether this branch of medicine alone should be underpaid. *Public bodies and charitable institutions* the cause of the attack. It is a commonly noted fact that the very sick seldom sneeze and they do not take cold easily, although they often suffer severely when a cold is epidemic, so perhaps a certain amount of vigour is necessary to develop a non-infectious cold, and it may be the expression of an effort of nature to protect the subject exposed, and may be compared to the uselessly excessive inflammation that often follows injuries. There is a tendency in writers on this interesting subject to rush from one extreme to the other, as our profession has so often done in the past. The infectious cold is now publicly recognised, but with our present knowledge I am sure it is premature to declare it to be the only cold and to advise general isolation. It would mean, amongst other things, the closing of all elementary schools whenever the wind was in the east and the turning out from public meetings any who coughed or sneezed. I believe that the key to the problem lies in differentiating the various kinds of colds, and if we can do this clinically the bacteriologist will have a far better chance of helping us.

I read Dr. Gardner's letter with great pleasure, and I sincerely hope that he may be right, for it would be a delightful thing to get rid of the "cold" bogey and to be no longer compelled to keep the youngsters off the wet grass. If we could obtain some positive knowledge on this subject we should remove a great reproach from our profession, for at present it is said that we know neither the cause nor the cure even of such a common thing as an ordinary cold.

I am, Sirs, yours faithfully,
O. Clayton Jones, M.B. Oxon.

Ilfracombe, Dec. 14th, 1901.

## CONTRACT PRACTICE IN NORTH WALES.

*To the Editors of* The Lancet.

Sirs,—I should be much obliged if you would allow me to make use of your columns to draw the attention of your readers to the following facts. Up to this year all the friendly societies in this town were attended by one firm of two brothers. During the year 1901 the various societies started a movement to change their club rules in order that each member might at the beginning of each year choose which of the five resident medical practitioners he would have to attend him in case of illness. Under the old rule the rate of pay was 3*s.* 6*d.* per member per annum. After two of the societies—of which there are three in question—had altered their rules to this effect the resident medical practitioners met in conference and decided that under the new conditions 5*s.* per member per annum would be the minimum that they could accept, and an intimation to this effect was made to the societies. This they all rejected as being an exorbitant demand, and instead of sending the new rules for ratification to the Registrar of Friendly Societies they tried to get an outside practitioner to take them all at the old rate. I am glad to be able to state that one gentleman with whom they were in communication has, after becoming acquainted with all the facts, absolutely declined to accept the post.—I am, Sirs, yours faithfully,

Dolgelly, Jan. 10th, 1902. A Dolgelley Practitioner.

---

**A Patient's Aversion to Medical Men and its Consequence.**—Last week we referred to the death of a man at Derby who preferred to be attended by an unqualified practitioner. On Jan 11th the coroner for West Bromwich held an inquest at the Dartmouth Hotel, West Bromwich, concerning the death of a woman, aged 45 years, who died suddenly on Jan. 9th. The deceased had been ailing since August last and had occasionally seen a medical man, but had not during the last four months received proper medical attention, because she had a strong aversion to medical men. In spite of protest by her husband and daughter she always declined to see a qualified medical man, but becoming worse on Jan. 9th a medical man was called in The woman, however, died from heart disease. It was stated that the deceased was a very hard-working woman and would prefer to spend what money she had on her family rather than on medical attendance for herself. The coroner thought that in these cases the services of the parish medical officer should be obtained and that his attendance would avert the necessity of holding a public inquiry. The jury returned a verdict of "Death from natural causes," but added that the woman's end was brought about in a measure by over-work and self-neglect.

## THE ORGANISATION OF THE PROFESSION.

(From our Special Commissioner.)

### The Working-classes and the Birmingham General Dispensary.

Now that the practitioners of Birmingham have organised a strong medical union the problems to be solved assume a practical as well as a theoretical interest. Prominent among these is the question of the Birmingham General Dispensary. The importance of this institution can be gathered from the figures given in the last annual report. The receipts from all sources then amounted to £9554. The cost of the surgeries, the surgical appliances, and the drugs is put down at £1786. The consulting physician received £157 10*s.* and the consulting surgeon £157 10*s.* The salaries of the resident medical officers amounted to £2179, those of the dispensers to £836; the secretary's collecting office expenses to £598; the servants' wages to £729; and the cab-hire for the medical officers to £298. The rest was spent in advertisements, insurances, coal, gas, and taxes, and £105 were given to the District Nursing Society. There is generally a good credit balance carried over. The number of patients treated on presentation of a ticket has greatly increased. In 1880 there were 17,759 such patients. In 1890 they increased to 26,030 and in 1895 the figure was 32,774. In 1900, the number of patients admitted by ticket was 43,678, which is an augmentation of 2513 on the previous year. It will be seen, therefore, that the number of patients has more than doubled in 20 years. Can it be said that the number of persons who are worthy subjects of charity has more than doubled in the last 20 years? Has England sunk so low, has the misery in these islands become so wide-spread, that charities must be doubled in extent so as to bring the needed relief? Evidently this is not the case and the increase of patients at this dispensary has no relationship whatsoever with the increase of poverty. The very reverse is the case. Whatever may be the effect of the war on the wages and incomes of the inhabitants of Great Britain taken as a whole, it is absolutely certain that the inhabitants of Birmingham have been reaping a golden harvest. Never were the working classes there so fully employed and never was so much overtime done. If other industries have suffered that of the manufacture of small arms, of cartridges, and of dynamite, for which Birmingham is the centre, has been overwhelmed with orders and with work. Therefore the need of charity in the form of medical relief should have considerably decreased while the war provided so much extra employment But we find, on the contrary, that there were 2513 more patients who applied to the Birmingham General Dispensary in the year 1900 than in the year 1899. Evidently, therefore, the increase of patients is not due to an increase of poverty. Consequently there must be an abuse of this charity.

The rule is, that every person who subscribes a guinea to the dispensary may vote for the election of the governors, and he receives eight tickets, which he may give to poor patients, and such patients will be entitled to medical treatment for one month. But it is also stated that "every governor recommending a person as a patient shall satisfy himself that the person is a proper object for charitable relief." If these were the only rules then there would be no further abuse than that which under similar circumstances arises all over the country, and which is due to indiscretion and carelessness on the part of those who give away the tickets. In our series of articles on Hospital Abuse numerous instances of such indiscretion have been given, and, taken by itself, this constitutes a serious grievance. Nevertheless this is a comparatively easy matter to deal with. The fault clearly lies with those who give away the tickets They should be more careful and should take the trouble to ascertain whether the persons among whom they distribute the tickets are really worthy subjects for charitable relief. These remarks do not apply especially to Birmingham or to dispensaries, but also to hospitals and to every part of the kingdom where tickets are given in exchange for subscriptions to charitable institutions. The grievance special to Birmingham and which accounts for the enormous increase of patients attending at the Birmingham General Dispensary finds its origin in the weekly collections made in factories soap and warm water and, in the cases of the men, shaved; the region where vaccination was to take place was then well rubbed with hot boric acid solution (saturated) and afterwards dried with boric lint. The vaccine was placed on the skin in three places and the epidermis was scratched through the vaccine with a blunt lancet; hardly any blood was perceptible, merely a slight discolouration appearing. The ages of the persons revaccinated were between 15 and 65 years, and all ranks of life were represented, from the higher official at £1000 a year to the engineer's labourer at 30*s* a week. In these cases and in a large number of others I have had no failure, every case, in all sorts and conditions of men and women, taking well without undue inflammation or enlargement of glands. The women have all been vaccinated on the shoulder at their own request and have as a consequence suffered much more than the men who have been vaccinated on the outer side of the left forearm where the vesicles cause little inconvenience.

I have carefully tested the results of the use of shields or covering of any kind during the last three months and I am confirmed in my previous conviction that every appliance of the sort is injurious and harmful, the inflammation being increased by heat or pressure or by both; great pain is caused by lint sticking to the vesicles, and I have especially noticed that the wire guards by circumscribing the area of the swelling cause very much increased suffering. I have had the best results when the following directions have been carried out: the undervest sleeve should be turned up and nothing worn under the sleeve of the white shirt which is always very loose; where a coloured shirt is worn, a piece of clean, soft, old cambric handkerchief should be tacked to the inside of the coloured sleeve The vesicles are in this way hardly touched by the sleeve and the arm is kept cool. The only application I recommend is a liberal and frequent dusting with vinolia powder and I find that with these precautions the vesicles are, as a rule, dry and unbroken.

In large offices there will always be a certain number of conscientious objectors When I began at the Ocean Office many declined to be vaccinated, others went to private vaccinators, but when the results of the arms were seen, everyone came to me; and I mention this as I feel sure that the results were due to careful antiseptic methods, the lancet being sterilised with boiling water between each separate vaccination.—I am, Sirs, yours faithfully,

ALBERT BENTHALL, F.R.C.P. Edin.

*Tavistock square, W.C., Jan. 12th, 1902.*

## THE SANITARY CONDITION OF LEICESTER INFIRMARY.

*To the Editors of* THE LANCET.

SIRS,—As I notice an article in THE LANCET of Jan. 11th, p. 113, on the sanitary condition of Leicester Infirmary, summarising the results "of a joint conference between the weekly board and the honorary medical staff of the Leicester Infirmary" with respect to my recommendations as to the sanitary condition of that institution, which report agrees with almost all of my recommendations, but in which there is a sentence which you have quoted as follows:—

> Sufficient cause has not been shown to justify Professor Corfield's opinion that "the whole of the present drainage arrangements must be condemned and removed entirely and new drains laid, &c."—

I write to inform you that my reason for giving that opinion was that all the drains tested by the architect or by myself were found to leak badly—a fact which, in my opinion, quite justifies the recommendation, which is, I consider, one of the most important and necessary recommendations in my report. It is nowadays axiomatic amongst sanitarians that the drains, especially those of such an institution, whether inside or outside the building, should be watertight.—I am, Sirs, yours faithfully,

W H. CORFIELD.

Consulting Sanitary Adviser to His Majesty's Office of Works.

Savile-row, W., Jan 15th, 1902

## ARTIFICIALLY MATURED (?) WHISKY.

*To the Editors of* THE LANCET.

SIRS,—I notice in THE LANCET of Jan 11th, p. 109, a short annotation on the artificial maturation (?) of spirits. Although no reference is made, I presume the article was partially occasioned by the paper which I read before the Society of Chemical Industry on Monday, Jan. 6th. I would point out that the process I proposed affected only the aldehydes of the spirits, the higher alcohols, fatty acids, esters and basic constituents remaining untouched. Under no circumstances can I think it very advantageous to leave in aldehydes, especially furfurol, when one considers the work of Curoi, Magnan, and Laborde and the later publication of Brunton and Tunnicliffe in THE LANCET of Dec. 8th, 1900, p. 1643. As a chemist I should be very glad to know what are the opinions of physiologists on the effect of aldehydes.

I am, Sirs, yours faithfully,

East London Technical College, Jan. 11th, 1902 J. T. HEWITT.

## THE DANGERS OF A COMMON COLD.

*To the Editors of* THE LANCET.

SIRS,—Dr. H Willoughby Gardner, in his interesting letter in THE LANCET of Dec. 14th, 1901, p 1697, advances many striking arguments, but he does not prove his thesis. That there is an infectious cold no medical man who goes about with his eyes open, as your correspondent says, can doubt, but the question is whether this is the only kind. The immunity of isolated bodies of men may show that this is the commoner kind, but as the examples given were lusty adults they do not prove that it is the only kind. Men in good condition seldom catch cold. It is a rare thing for a rowing crew to catch cold, although the coxswain and coach often suffer The stories are incomplete, for they do not show that this complaint existed in the European settlements where the travellers caught their first cold. In the case of Conway's men it was a "bad cold," and to make the story complete we should know whether bad colds were troubling the little settlement. It would be a curious complication of the question if temporary immunity leads to a worse cold in the end. The immunity in long sea-voyages is better evidence, for the manner of life is that of civilisation, but the ordinary sailor is notorious for his dislike to ventilation; so here it is difficult to understand why colds, if infectious, should die out, for one attack certainly does not protect. If the immunity of open-air sanatoriums is complete this is strong evidence, especially as they receive so many catarrhal subjects; but the inmates are living an artificial life and their immunity may be due to other causes than the absence of infection. They eat largely without indigestion, but this does not prove that dyspepsia is due to specific infection. On the whole, the evidence of "no infection, no cold" is strong, but not conclusive.

On the other side is the weight of almost universal opinion in the past, both lay and medical, which ought to go for something, although Dr. Gardner may well smile at the ready histories of exposure given by subjects of an obviously contagious cold; there is similarly a history of an accident connected with most gouty joints But there is other evidence. Colds, especially amongst the children of the poor, are far more common when the wind is in the east and when, therefore, sudden chills are common. A cold wind will set up eczema and conjunctivitis and therefore it seems probable that it may cause catarrh of the nasal mucous membrane. The phenomenon of what is termed "hay fever" seems to prove that coryza can be set up by causes other than infection, and in many patients a cold much resembles an attack of hay fever. The variations in duration of the incubation period, and of the length of the established attack, the common occurrence of abortive attacks, and the fact that one attack does not protect, all militate against the view that there is a single definite infection.

I feel sure in my own mind that there are persons, for example, who suffer from a cold if they sit in wet boots, and that the symptoms come on within a few hours and are generally ushered in with sneezing; I think this happens with sufficient certainty to exclude infection. Of course, there may be an infection generally distributed throughout the civilised world, and a chilled blood-stream may let this enemy in, but this is hardly what is meant when colds are said to be due to a specific infection. More probable is the view that these rapidly developing colds are, like migraine, a disturbance of the vaso-motor system. A recent writer states, I know not on what authority, that "sneezing is a sign of life in the east but of death in the west" It certainly is a sign of a commencing cold in the west, and when this symptom commences almost immediately on exposure to cold it is difficult to believe that infection has any part in at the dispensary there is a more lavish distribution of bandages and ointments, &c. Therefore, many workmen prefer paying to go to the dispensary instead of subscribing to a benefit society or to a medical aid association. Of course, if they went to the dispensary and offered to buy a ticket it would be refused, but the secretary of a works club, if he has exhausted his tickets can get others without giving another guinea, for he can buy them for 3*s.* 6*d.* each, and is then at liberty to give them or to sell them to whom he pleases. Thus a workman can buy a ticket from the secretary of his club, though he cannot buy one from the dispensary. This roundabout process altogether fails, however, to impress on the workman's mind that he is in receipt of charity. He does not understand charity that costs him 3*s.* 6*d.*, but he quickly realises that he is getting medicine and medical advice at a very cheap rate. As, on the other hand, the medical men have not yet made it evident that they object to this, the workmen naturally conclude that the medical men know their business best and therefore do not scruple to avail themselves of the advantages within reach.

Undoubtedly it is partially the medical men's own fault that the system has been allowed to mature. The medical officer accepts service with the dispensary because he imagines that the patients whom he will see are only poor people who could never consult a private practitioner, and that therefore he is not interfering with or underselling his brother practitioners. Some medical men only go to the dispensary for a few months so as to lend a hand, as they imagine, in a charitable work. Now it will be the business of the Birmingham and District Medical Practitioners' Union to make it clear that the dispensary is no longer wholly and solely a charity, but that in many instances it competes disastrously with the general practitioner. It will be its mission to find, first, a remedy for the abuse, and, secondly, a means of enforcing this remedy, and it must be confessed that this is no easy task. Evidently a wage-limit, or something equivalent to that, will have to be imposed.

But this is far from being the only task that has to be taken in hand. The battle of the clubs will have to be fought on a very large scale, for the abuses arising out of the contract system are also wide-spread throughout the district. Nothing can be accomplished unless it be with the aid of a strong organisation and united action. Now, however, that more than 200 general practitioners are in union there should be less difficulty in inducing the remainder to join also, and thus a practical unanimity may be secured in course of time. In these endeavours the Birmingham and District Medical Practitioners' Union will be supported by the organised members of the profession throughout the kingdom, and the medical profession generally will unite in wishing it every success.

# NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Plague Epidemic.—The Malarial Convention at Nagpur.—Indian Jails.—Condition of the Jails in Bengal.—The Continued Famine.*

OWING to the Christmas holidays the plague figures have not been published in time for the mail, but detailed returns since Dec. 14th show that there has been an increase of the epidemic in Bengal, in the North-West Provinces, and in the Madras Presidency, while a decline is recorded for the Bombay district. In Mysore and the Punjab the continued high mortality shows that the disease is but little under control, although the latest figures from the Punjab point to some improvement. The Kapurthala State has become infected for the first time, and the Patiala State shows an increase in the mortality. In Bombay city the deaths from plague continue about the same, but in Calcutta there has been a drop during the past week to 15 deaths. The general mortality has again advanced in Bombay but is exceptionally low in Calcutta. In the latter city the rate is about 32 per 1000, while in the former it is about 52 per 1000. The returns are now calculated according to the results of the recent census, so that comparison with former years is unsatisfactory.

A Malarial Convention is to be held at Nagpur, Central Provinces, on Dec. 27th and following days, when the attendance of medical men from all parts is expected. In the Nagpur Central Jail is a large collection of malarial cases as well as a collection of many varieties of mosquitoes. The members of the Malarial Commission of the Royal Society will be present, so that we may expect some interesting discussions.

A resolution of the Government of India on the reports on the administration of jails in the provinces of British India for the year 1900 refers amongst other things to the increase of 21 per cent. in the admissions, which is attributable to scarcity and high prices. In Burma and Assam, where these influences were absent, there was no increase. There was an increase of 40 per cent. in the numbers convicted of offences against property, and there was an extraordinary increase of no less than 57 per cent. in the number of juveniles sentenced to imprisonment. The percentage of previous convictions of those admitted to jail was 14·15. In this connexion it is satisfactory to hear that more attention is being given to finger-tip impressions, and that a larger number of prisoners were identified by these means. The sickness and mortality tables show a death-rate of 33·46 for all the jails, which is higher than that of the previous year but is said to compare favourably with the rate of mortality recorded among the free population (38·6). This is hardly a fair comparison, because infants, young children, and women in child-birth, not to speak of chronic invalids (too ill for crime), are excluded. The famine is put down as the cause of the increase in admissions; the accommodation of the jails was greatly strained and the high prices ruling occasioned an increase in the cost of maintenance.

In the current number of the *Gazette of India* is given an abstract of the sanitary sheets of the most unhealthy jails in Bengal. They are nearly all described as overcrowded for some period during the year. In the Mymensing Jail temporary buildings were necessitated, but they are described as unusually damp and dirty. In the Dacca Central Jail return it is said that the sanitary defects in the surroundings were too numerous to mention. At Chittagong the rice was poor in quality, badly stored, and weevil-eaten. At Backergunge the water-supply is obtained from the tanks and is very bad. At Burdwan the ventilation of the wards is very defective and the ground around the jail is waterlogged for months in the year. At Rangpur the climate is extremely malarious and almost all the inhabitants suffer. At Ranchi there was an epidemic of pneumonia. At Chupra the country around is waterlogged all through the rains and the water-supply is very unsatisfactory. These few extracts show what an enormous amount is required to be done to improve the sanitary condition not only of the jails but of the towns in which they are situated. The prisoners must offer an immense field for clinical investigation.

The famine figures show a slight increase. There are still nearly 100,000 persons under relief.

Dec. 27th, 1901.

# MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

*Proposed University for Manchester.*

THE special meeting of the Court of Governors of the Owens College held on Jan. 7th was signalised by the passing of an important motion, closely resembling that of the Owens College Associates recorded in THE LANCET of Jan. 4th, p. 60. It was moved by Mr. E. Donner, seconded by Professor Tout:—

> That the time has arrived when steps should be taken to secure that there should be, as originally proposed by the Owens College, an independent university in Manchester.

16 members voted for the motion and none against it. On the 10th a special meeting of the Victoria University Court was held at the Owens College to discuss, and if need be to take action on, the report of a committee appointed on June 29th to consider the course to be taken if University College, Liverpool, should apply for a university charter. The questions given in the report for solution were whether (*a*) the three colleges—Owens, with those of Liverpool and Leeds—should remain as constituent colleges of the university; or whether (*b*) there should be a separate university in Liverpool and "a university in Manchester without liability to admit or remain in association with any other college," and also "a university established having its seat in Leeds." The first alternative may be

and workshops on behalf of the Hospital Saturday Fund. The working-classes are imbued with the principle that payment confers the right to vote, a principle confirmed by the rule of the dispensary which gives a vote and eight tickets to the donor of one guinea. But as no individual working-man was likely to give a guinea it was not supposed that working-men would elect governors and they were still less likely themselves to become governors. In this, however, no account was taken of the spirit of organisation bred out of the Hospital Saturday Fund. The weekly levies would not have been tolerated for so long had they not been made to confer rights; and so large is the sum thus obtained that the working-classes are beginning to imagine that they have bought up every institution in the town. The working-man is far too well acquainted with the advantages of organisation to give his pennies directly to the dispensary. That would be an act of pure charity on his part, for he would receive nothing in return. He therefore institutes what is called a works club. All the workmen engaged in a factory pool their subscriptions till they have collected a sum of perhaps £2 2*s.* for the dispensary, and then the secretary of the works club hands over this sum to the dispensary and consequently receives 16 tickets and is entitled to vote for the election of governors. Thus the working-men not only vote, but they have elected fellow-workmen as governors of the dispensary. These working-men governors are by far the most energetic and regular attendants on the committee of management. They have a personal interest at stake, whereas the rich people who subscribe guineas do so purely from benevolent motives and do not anticipate utilising the dispensary for their own purposes. The workmen, on the contrary, look upon the dispensary as a means of obtaining cheap medical attendance and of thus economising the medical fees which they would otherwise have to pay. They do not give the tickets they receive in exchange for the guineas which they have collected to persons who are "proper objects for charitable relief," but they utilise them for themselves or their families.

The idea, however, that the dispensary was a charity was somewhat humiliating, and the workmen having obtained representation on the board of management the rules were forthwith altered. The tickets given to the secretaries of the works clubs no longer bear the inscription, "a proper object for charitable relief," but the words, "whom I believe to be deserving of medical relief." A gentleman who gives his medical adviser a liberal fee is certainly deserving of medical relief, and the workman who has subscribed regularly to his works club does not fail to consider himself equally deserving of medical relief. He pays less, but the relief is given in a less costly manner. Consequently the workman concludes that he only receives that to which he is fully entitled, and he would be deeply offended if he were considered the recipient of charity Yet it cannot be insisted too often and too clearly that he *is* in receipt of charity. The charity is twofold: it is a charity in hard cash and a charity in the form of underpaid or partially gratuitous medical service Eight tickets are given for a guinea, that is 2*s* 7½*d* per ticket. The annual report says that in 1900 the average cost of the patients was 3*s.* 9·2*d.*, or 1*s* 2*d.* less than it was in the previous year. Therefore each patient cost in hard cash and on an average over 1*s.* last year, and over 2*s* the previous year, more than the sum actually paid for him, and this does not take into account the value of the professional advice which was given and which should represent a much larger sum. Therefore the dispensary remains a charity in spite of the pretension of the subscribers to works clubs that they pay for what they receive.

One of the worst features of this system and one which works out very injuriously to the interest of the medical profession, is that it gives relief just when it is least needed and does not give relief when it might be legitimately claimed It has been calculated that on an average the members of works clubs can receive two tickets per annum. As this entitles the bearer to a month's treatment for each ticket he need not pay medical fees when suffering from an ordinary illness. This, however, is just the time when artisans and other persons of small means can afford to pay medical fees. On the other hand, should the illness be of so prolonged and serious a character that it lasts more than two months, then even those who when well are in receipt of good wages may be excused if they can no longer continue to pay for medical attendance. But it is just at this moment that the assistance rendered by the works club fails. The patient, having had his two tickets for the dispensary, cannot claim more, and yet by that time his resources are exhausted. Thus he obtains charity when he has no legitimate claim and when at a later period of sickness he might fairly be considered to be a worthy subject for charitable assistance it is withheld from him It will be seen that the system is altogether wrong. What was intended as a pure charity has become in part a provident organisation. The subscribers to the works clubs take great care to let the medical officers of the dispensary know that they are not like the other patients, but have paid. By this they infer that they are not in receipt of charity; but this is a false conception. The figures given above show that they are in receipt of charity, and the ugliest feature of the abuse is that these thrifty, industrious, and careful workmen who have the forethought to subscribe regularly to their works club are, by receiving this charity, depriving the poor who really need it and for whom it was intended. The genuine poor find considerable difficulty in getting tickets for the dispensary. They must go about and beg for them, whereas the thrifty and well-to-do artisan has his ticket waiting for him at the works where he is employed. He has but to say a word and it is given to him, for he can claim it as a right. It is only when he ceases to be in a good position, when prolonged illness has exhausted his savings, when he really and urgently needs help, that the help is no longer forthcoming. It is for men in this latter stage, for those who are in real distress, that the medical officers are willing to give their services for nothing or for very reduced rates of payment. As matters now stand the opposite obtains. If there were not so many well-to-do patients frequenting the dispensary the whole, instead of only a part, of the resources of that institution would be available for the relief of the genuine poor. On the other hand, the general practitioner would have many more private paying patients among that class which can well afford to pay at least for a short period of time the usual small fees charged. It is only when the resources of the patient are exhausted that he should be allowed to claim the assistance of a charitable institution such as the Birmingham General Dispensary.

There are actually 11 resident medical officers employed by this institution, and, if properly managed, it would afford a very good opening for young practitioners. The medical officers are first engaged for £150 a year and £30 more are allowed for cab-hire. As no account has to be rendered it is probable that this latter sum is not all spent in cabs. Then the medical officer has a residence provided for him at the central offices in Union-street. After a while he is promoted to one of the branches and on removing he generally obtains an increase in his salary of £20. Of course, he is not allowed to have any private practice After one or two years of branch work he may suggest another increase and sometimes he will get it, sometimes it will be refused When accorded it generally amounts to another £20. Out of the 11 resident medical officers there are now four who have obtained this second increase in their salaries. The patients are well disciplined. The door for receiving messages asking the medical officer to call on a patient is closed punctually at 10 in the morning. The medical officers have, as a rule, about 15 visits to pay every day; but, of course, in this there is no regularity, and sometimes there are as many as 45 visits to be paid in a single day. Generally speaking, however, these patients can all be attended to in the morning. Then the out-patients come to the surgery at 2.30 P.M. As the greater number are suffering from chronic diseases—bronchitis, phthisis, &c.—it is frequently only necessary to repeat the mixture previously prescribed. Such patients can be disposed of very rapidly and thus a considerable amount of time may be devoted to a new and interesting case This latter consideration may contribute to explain the popularity of the dispensary. The ordinary club medical officer is likely to be in a hurry to go to see his private and paying patients. Time is of greater object to him. The dispensary medical officer is young, is seeking to acquire experience, he has no private patients, the whole afternoon and evening are before him, and he is but rarely called out at night. This is all excellent in its way and very fortunate for the poor, but it altogether misses its mark if it attracts well-to-do patients. There is also an impression prevalent that the medicines given out at the dispensary are of a superior quality. This is erroneous, but nevertheless it serves to attract many patients. It is, however, true that there were five candidates, and eventually Dr. W. H. Cooke and Mr. H. L. Brownlow were elected.

### *The Prevention of Tuberculosis.*

A meeting was recently held at Wells, Somerset, under the presidency of the Mayor, with the view of considering the best means of promoting the interests of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis in Wells, Shepton Mallet, and Glastonbury districts. Amongst those present were the Bishop of Bath and Wells, the Dean of Wells, Dr. W. Fairbanks, Dr. W. A. Lauder Smith, and Dr. L. A. Weatherly. The last-named in the course of his speech stated that a site had been purchased at Winsley for the sanatorium, and he added that the committee had a balance in hand of nearly £5000, but it had been decided not to erect the building until they had at least £9000 promised over and above the expenditure in the purchase of the site. After some discussion it was determined that a local committee should collect subscriptions towards the Winsley sanatorium.

Jan. 13th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Glasgow University.*

A MEETING of the Glasgow University Court was held on Jan. 9th. The subject of chief interest was a discussion on the report of a committee dealing with the use of the apparatus in the engineering laboratory. The laboratory has cost £40,000 and is an annual charge upon the University funds to the extent of some £600. Hence it is felt in some quarters that it ought not to be monopolised by the professor of engineering. Under the present arrangement the professor has sole control of the laboratory and may use it not only for teaching but also for his own private work, and for the latter purpose may employ technical and other assistants. In these circumstances it is held that a proportion of the fees earned should be paid into the University chest and that a special committee should be placed in charge of the laboratory to regulate the use that is to be made of it apart from teaching purposes. In the course of the discussion the question was raised as to whether it was legally competent for the court to adopt this position, and the matter was therefore adjourned in order that a legal opinion might be obtained.—Mr. R. M. Mitchell has been re-appointed to the court as one of the representatives of the town council for a further period of four years.—The recommendation of the finance committee that a sum of £5000 should be voted to the University led to a long discussion at the meeting of the town council on Jan. 9th, and was ultimately carried by a large majority. The money is placed at the disposal of the authorities to be used either for the improvement of the general equipment of the University or for the establishment of a lectureship on social philosophy. In connexion with this vote an appeal has been issued from the University asking for contributions to a further sum of £5000 in order that the lectureship may be at once founded with an endowment of £350 per annum. Towards this Sir James Bell, Bart., has given a donation of £1050; other sums amounting to £500 have also been promised.—Professor J. G. McKendrick, who has been suffering from an attack of erysipelas, is making satisfactory progress towards recovery; he hopes shortly to resume the duties of his chair.—Professor Bower delivered one of the University free lectures on Jan. 13th, taking for his subject "A Grain of Wheat." In speaking of wheat as an article of diet he described it as being rather deficient in proteids and as having too large a proportion of carbohydrates with some deficiency of the fats. He pointed out that the Italian fared better on his macaroni, prepared as it was from highly nitrogenous wheats, than did the Glasgow children on white bread; for these a return to porridge and milk would be an enormous advantage. Professor Bower also discussed the economic aspect of his subject and urged the establishment of stores of wheat to secure an abundant food-supply in the event of war.

### *Bequests to Glasgow Institutions.*

In accordance with the directions of the will of the late Mr. William Langlands of Glasgow the following legacies have been distributed:—Glasgow Royal Infirmary, £1000; Western Infirmary. £1000; Sick Poor and Nursing Institution, Training Home for Nurses, and Cancer Hospital, each £500; Sick Children's Hospital, Home for Incurables, and Quarrier's Homes, each £250. Various other charitable and philanthropic institutions receive bequests, making a total of over £9000

### *Unusual Legal Action.*

An action of a somewhat unusual nature has recently been successfully instituted against the Corporation of Glasgow. The pursuer, a labourer in the employ of the corporation, was during the summer of last year, in the course of his duty, engaged in making concrete blocks and in painting copper bonds. As a result he suffered from the consequences of metallic poisoning. In his claim against the corporation he urged that this resulted from the paint supplied to him and contended that it was the duty of the defenders to have warned him of the risks to which he was exposed. As they did not do this they were, he argued, responsible for the harm which he had sustained. The case has been settled out of court, the defenders paying to the pursuer £225 in satisfaction of his claim.

### *Society of Antiquaries of Scotland.*

At a meeting of this society, held on Jan. 13th, Dr. Thomas H. Bryce of Glasgow University gave an account of a series of explorations in the Cairns of Arran and described the human remains there discovered. The work was commenced on the initiative of Dr. Ebenezer Duncan and has received financial support from the Society of Antiquaries. The results, together with those obtained in 1860 by Dr. James Bryce when investigating the stone circles of Arran, give a fairly complete view of the prehistoric sepulchral monuments of the island.

### *The Carnegie Trust.*

A meeting of the executive committee of the Carnegie Trust was held in Edinburgh on Jan. 13th, Lord Elgin being in the chair. The secretary and treasurer submitted their reports for the period ending Dec. 31st, 1901. These showed that fees had been paid by the trust for 2441 students, the sum thus expended amounting to £22,941 16*s.* 6*d.* The annual meeting of the trustees is to be held in London, and the report will probably be made public after this meeting.

### *King's College Class, Aberdeen, 1864–68.*

For the first time since it separated the King's College Class, 1864-68, met for dinner in the Palace Hotel on the evening of Jan. 10th. Professor Davidson (Aberdeen) was chairman and Dr. Thomas Milne (Aberdeen) and the Rev. Dr. Bruce (Banff) were croupiers.

### *Report of the Aberdeen Public Library.*

The arrangement with the Aberdeen University library by which, on payment of a modified subscription of 5*s.* per annum, anyone entitled to borrow books from the public library may become entitled to borrow also from the University library, has worked smoothly throughout the year and has been taken advantage of by 24 borrowers, to whom 193 volumes were issued.

### *Aberdeen University Extension Fund.*

The students of the various faculties at Aberdeen University have subscribed the sum of £205 towards the extension of the University buildings. The list will close on Feb. 20th.

Jan. 13th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Mercer's Hospital, Dublin.*

A LARGE number of the friends of, and subscribers to, Mercer's Hospital, Dublin, were invited by the governors to be present on Jan. 10th on the occasion of the opening of a new children's ward by Lady Arnott. Lord Justice Fitzgibbon occupied the chair, and in his address alluded to the fact that the hospital, founded in 1734, was one of the oldest institutions of its kind in Dublin. Lady Arnott, after a few kindly remarks as to the importance of hospital charity to children, declared the new ward open. Mr. T. W. Russell, M.P., as one of the governors of the institution, proposed a vote of thanks to the medical staff and subscribers and made interesting reference to his experience considered as out of court. Liverpool will without doubt have her university and no one can say that she is unworthy of it. Nor is there any need to attribute her wish to local jealousy, though Sir William Houldsworth said that "they were told that Birmingham had got a university and that Liverpool would have one. ...... It seemed to him merely a question of rivalry between these great towns." After much discussion paragraph (*b*) of the third section of the report was carried by a large majority, and the Victoria University Court has decided that Manchester shall have her own university. With Liverpool gone the Victoria University would then consist only of the Owens College and her younger sister at Leeds. Principal Boddington remarked that "it had been discourteously said that the Yorkshire College held to the federal scheme through consciousness of its own weakness." Whoever said that did not know Yorkshire. With its wealth, public spirit, and north-country grit Principal Boddington might well say that "he had not the slightest doubt that Yorkshire would do its share in the creation of a Yorkshire university." So disintegration is to be the order of the day. Many will regret with Lord Spencer, Sir William Houldsworth, Sir Ughtred Kay Shuttleworth, and others, the break-up of the university federation, and fear that it is not in the interests of higher education. On the other hand, great weight must be attached to the opinion of Dr. A. W. Ward, who was so long and intimately associated with the Owens College and the Victoria University as professor, principal, and vice-chancellor, and who now speaks with still more authority as Vice-Chancellor of Cambridge University, that he voted for a university for Manchester "in the full and firm belief that he was voting in the interests of higher education." The Owens College will therefore in all probability stand alone, as it did for four years, as the only college of the Victoria University. It was further resolved that a committee should be appointed to report on "terms and conditions," &c., that the Chancellor (Lord Spencer) should nominate a certain number of names, and then that he should fix the members to be appointed by each college. It may be hoped that the inevitable rivalry between these various universities will be directed towards raising and not lowering the standard of education.

### *The Manchester Infirmary.*

The question of re-building the Manchester Infirmary has not been brought prominently under notice for some time, though the urgent need for extension has long been the text of the honorary staff. An important paper, however, was read by Mr. W. T. Rothwell at a meeting of the Manchester Statistical Society on Jan. 8th, advocating the removal of the infirmary to Stanley Grove and the relief of the Free Reference Library and the Arts Gallery from their present cramped positions by building on the present infirmary site "a temple of learning and a palace of art" for their accommodation. A vote of thanks to Mr. Rothwell for his paper was moved by Mr. Marshall Stevens, who suggested "that a building of 20 storeys high might be built for the purposes suggested on the infirmary site." This grotesque and transatlantic suggestion was animadverted upon by Mr. T. C. Horsfall who seconded the vote of thanks. He said that there were plenty of buildings of 20 storeys, "but they were only found in towns where there was the grossest indifference to the conditions needed for human welfare." All will agree, I think, with Mr. Horsfall as to this matter. The deterioration of race takes place rapidly enough in our towns as they are at present, but it is slow compared with what it would be in a town consisting of 20-storeyed barracks. Dr. T. Harris said that increased accommodation was wanted and could not be provided by extension of the present premises. He did not think that the site was bad and it was central and convenient. A new infirmary was wanted and the accommodation could be increased from 300 beds to 500 on the Piccadilly site "without encroaching very much on the space available and without building 10 or 20 storeys high." The board of management is practically debarred from building on the space around the infirmary, and it is very questionable whether 500 patients could be accommodated in the best manner on the area covered by the present buildings. Though the present infirmary is central the objections to its removal are very much a matter of sentiment and Stanley Grove would come soon to be considered equally convenient. It is no doubt within the range of fog, which, however, is less pungent than that which at times almost chokes the patients in the centre of the city.

### *Small-pox.*

Small-pox is gradually extending in this part of the country. Manchester, which had been free for more than a year, has one case, one has occurred in Salford, four have occurred in the Stalybridge district, and one case has been notified at Bolton.

Jan. 14th.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

### *The New Chancellor of the University of Wales.*

THE Court of the University of Wales, at a special meeting held at Shrewsbury on Jan. 10th, unanimously elected H.R.H. the Prince of Wales as Chancellor of the University in succession to His Majesty the King who was Chancellor from the foundation of the University in 1893. A special meeting of the court is to be held to decide upon the town in which the ceremony of installation shall take place. The corporations of Cardiff, Aberystwith, Bangor, and Swansea have each extended invitations to the court. There are constituent colleges in all of these towns, with the exception of Swansea, and in Cardiff there is a medical school. Not the least noticeable portion of the proceedings at Shrewsbury was the graceful manner in which the senior deputy chancellor (Dr. Isambard Owen) responded to the deputations who urged the claims of their respective towns.

### *Small-pox near Swansea.*

A sudden outbreak of small-pox, directly traceable to a patient who was allowed to travel from London on the ninth day of the disease, has occurred at Ystalyfera, a parish in the Pontardawe Rural District, about 15 miles from Swansea. The patient was a girl who came to South Wales on Dec. 23rd, 1901, and from that day until Jan. 4th, 1902, she was in no way isolated, consequently eight persons, who had been in some way associated with her, have developed small-pox. There is absolutely no means of isolating infectious diseases of any kind in the Pontardawe district, although there is a working-class population of over 20,000 persons, and the constant inter-communication between the inhabitants of the district and those of Swansea renders it especially desirable that there should be means at hand for speedily checking such an outbreak as the present one.

### *Kingswood Sewage Works.*

The Royal Commission on Sewage Disposal has asked to have placed at its disposal the sewage works belonging to the Kingswood Urban District near Bristol for the purpose of taking records and making observations. The system of treatment is by means of a closed tank and continuous filtration upon the lines laid down by Mr. F. W. Stoddart, the city analyst of Bristol.

### *Weston-super-Mare Isolation Hospital.*

The Weston-super-Mare Urban District Council has decided to make no charge for the treatment in the isolation hospital of patients received from working-class families in which the bread-winner is earning less than 25*s.* weekly. Patients from other households will be charged upon a varying scale, with a maximum of two guineas weekly.

### *Vaccination Fees.*

The Axbridge Board of Guardians has declined to accede to the request from the Cardigan Board of Guardians to take steps to obtain the reduction of the fees paid to public vaccinators and vaccination officers. The Axbridge board very properly considered that such reduction would check rather than encourage vaccination and that it would not be desirable to reinstate the public vaccination station.

### *Cardiff Infirmary.*

Dr. O. T. Vachell has been elected honorary consulting physician to the Cardiff Infirmary upon his retirement as honorary senior physician, a position which he has held for the past 15 years Dr. Vachell has been officially connected with the infirmary for 23 years.

### *Royal United Hospital, Bath.*

At the meeting of the committee of the Royal United Hospital, Bath, held on Jan. 6th Mr. H. G. Terry and Mr. F. Lace, assistant surgeons to the institution, were elected full surgeons vice Mr. R. J. H. Scott and Mr. F. K. Green who have been placed on the honorary consulting staff. For the vacancies thus caused on the assistant staff

2. Anyone committing such offence and especially by communicating to a third party or knowingly communicating to any one of the parties interested before any examination the text or matter of the subject of examination, or who shall make use of false documents such as diplomas, certificates of birth, and the like, or who shall act as a substitute for the real candidate, shall on conviction be liable to a term of imprisonment varying from one month to three years and to a fine of from 100 to 10,000 francs or to any one of these penalties respectively.

3. Those found guilty of being accessories shall be liable to the same penalties.

4. Article 463 of the Penal Code is applicable to facts provided for by the present law.

5. The public action at law shall not estop disciplinary action in any case in which the law has provided for this latter course.

### *Chloroform Anæsthesia in Patients with Morbus Cordis.*
